# Today: The Force of Gravity

## **Last Time:**

- Inertia & Momentum
- Mass, Weight, weightlessness & orbits
- Newton's three laws of Motion

## **Topics Covered:**

- Conservation Laws
- What determines the strength of gravity?
- How does Newton's law of gravity extend Kepler's laws?
- How do gravity and energy together allow us to understand orbits?
- How does gravity cause tides?

# Newton & Newton's Laws of Motion

## How did Newton change our view of the universe?

- He discovered laws of motion and gravitation.
- He realized these same laws of physics were identical in the universe and on Earth.

**1<sup>st</sup> Law:** An object in motion will not alter its course unless another force acts upon on (inertia)

- *An object will move in a straight line unless acted on by another force...*

**2<sup>nd</sup> Law:** Net forces cause a change in the motion of an object (acceleration, where  $F=ma$ )

- *If an object's motion is changing, a force must be acting on it...*

**3<sup>rd</sup> Law:** Forces are paired and are equal in strength but act in the opposite direction (action-reaction pairs)

- *The forces must be equal and opposite...*

# iClicker Question

(Code = BC)

**Question:** If you take off in a rocket that is accelerating upwards...

- A. your mass increases and your weight stays the same
- B. your weight increases and your mass stays the same
- C. both your weight and mass increase
- D. both your weight and mass stay the same
- E. both your weight and mass decrease

# iClicker Question

**Question:** If you take off in a rocket that is accelerating upwards...

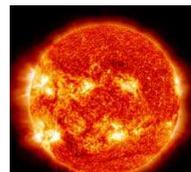

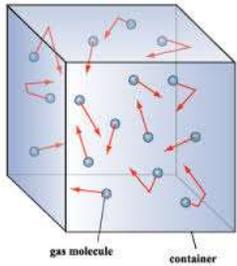

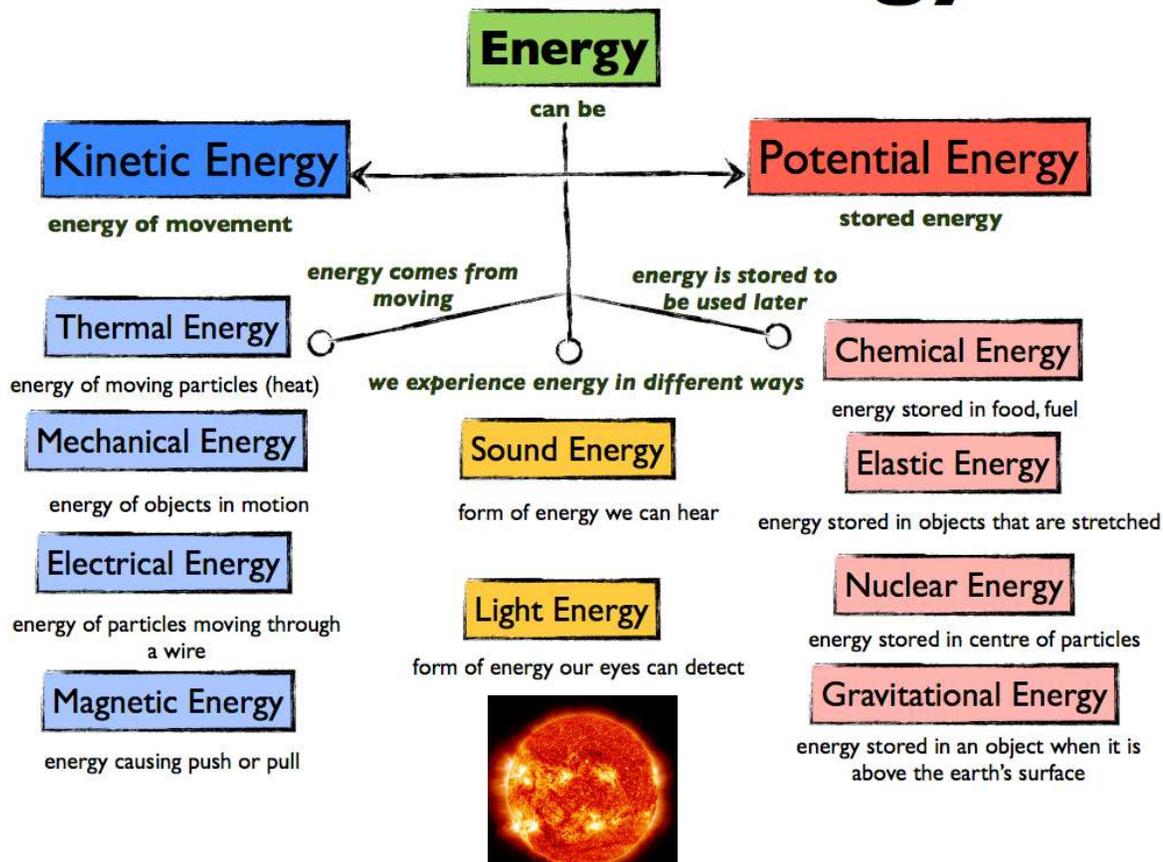

- A. your mass increases and your weight stays the same
- B. your weight increases and your mass stays the same**
- C. both your weight and mass increase
- D. both your weight and mass stay the same
- E. both your weight and mass decrease

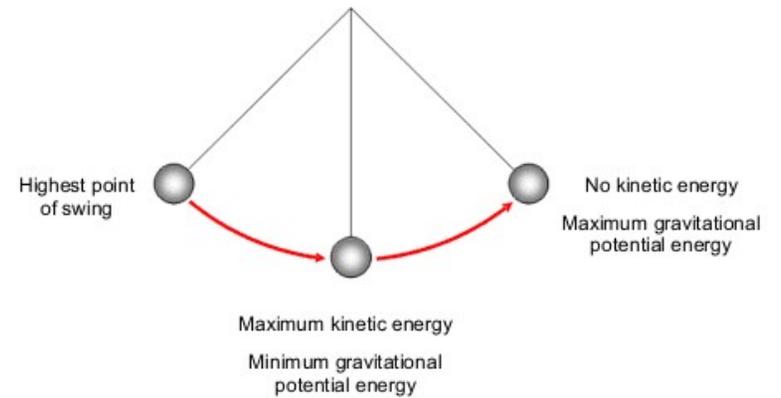

# Law of Conservation of Energy

“energy can neither be created nor destroyed; rather, it can only be transformed from one form to another”

## Forms of Energy

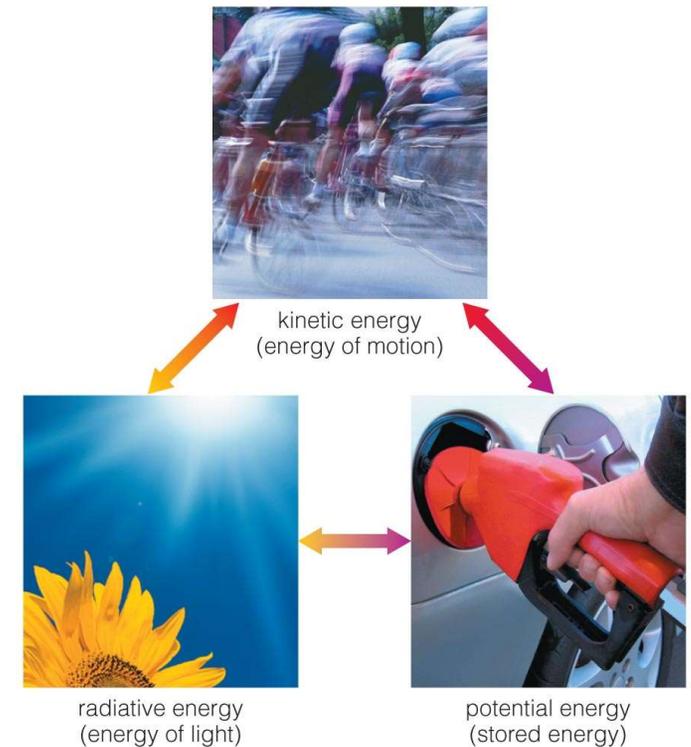

# Transfer of Energy Between Different Forms

Energy can be converted from one form to another.

© 2013 Encyclopædia Britannica, Inc.

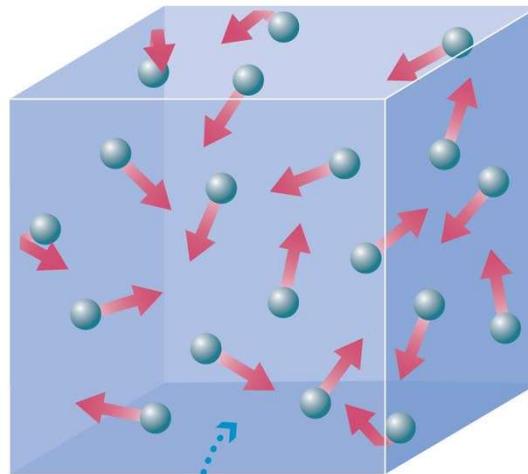

# Thermal Energy & Temperature

The collective kinetic energy of many particles  
(for example, in a rock, in air, in water)

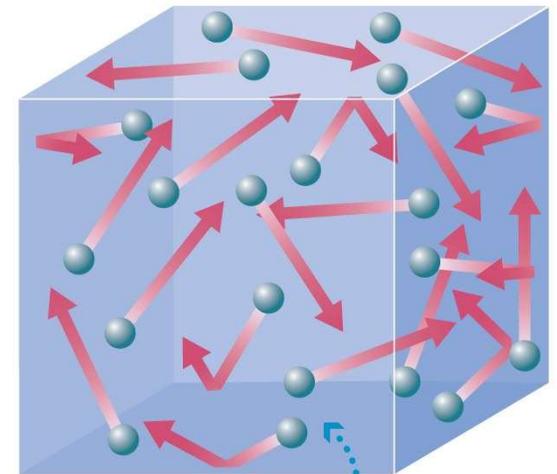

Thermal energy is related to temperature but it is NOT the same. **Temperature** is the *average* kinetic energy of the many particles in a substance.

**lower temperature**

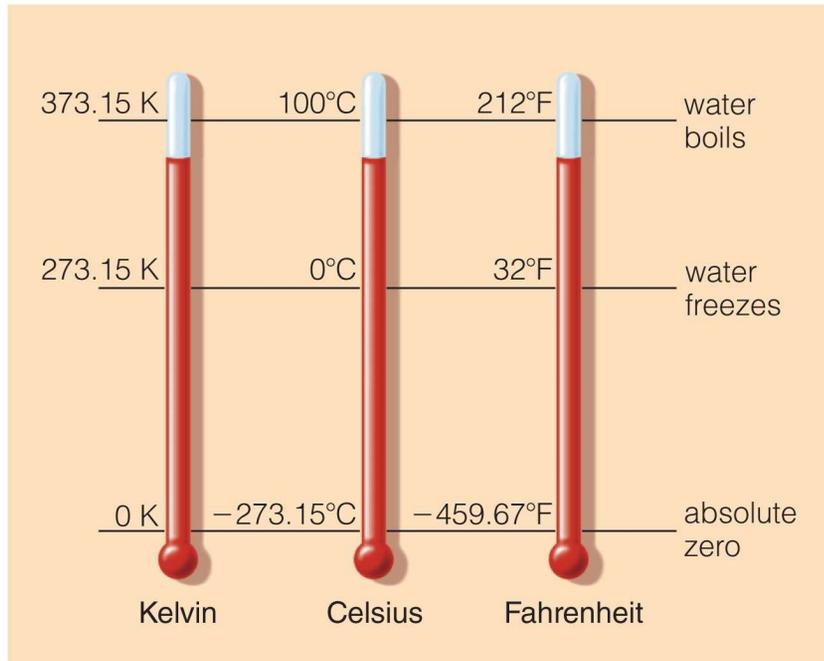

*These particles are moving relatively slowly, which means low temperature . . .*

**higher temperature**

*. . . and now the same particles are moving faster, which means higher temperature.*

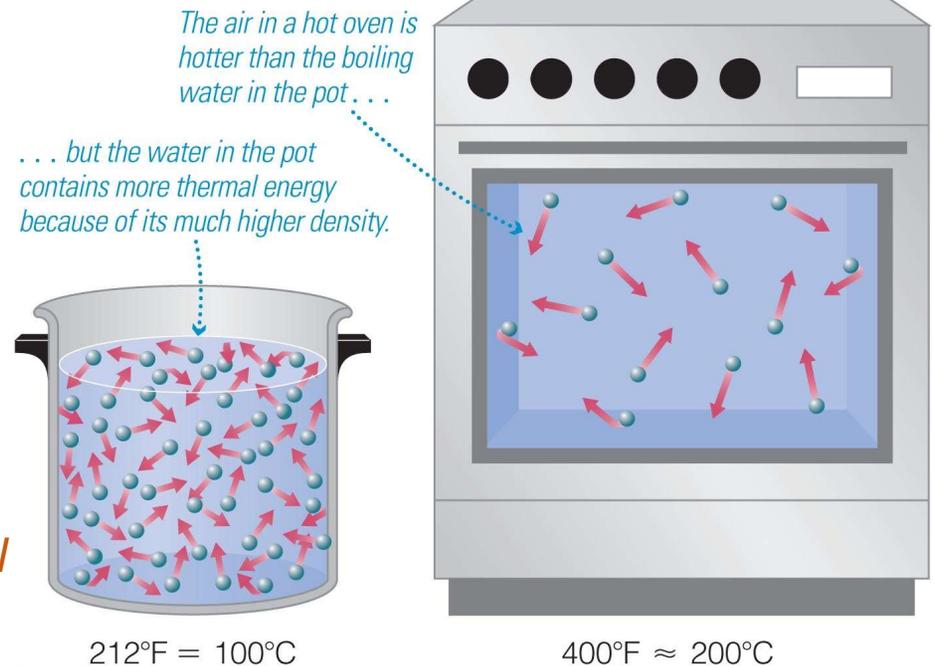

# Temperature Scales

**Nothing moves at zero degrees Kelvin**

*Thermal energy is a measure of the total kinetic energy of all the particles in a substance. It therefore depends on both temperature AND density.*

**Thought Question:** What would give a person a more severe burn? Exposure to steam at 100 °C or water at 100 °C?

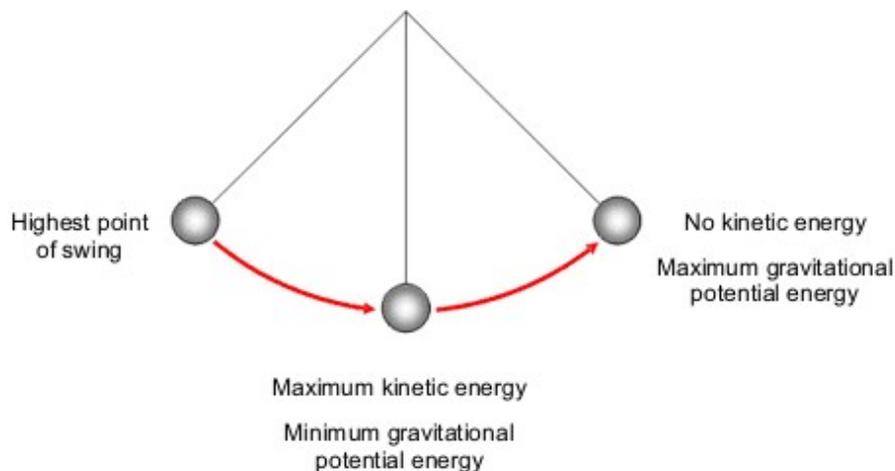

# Gravitational Potential Energy

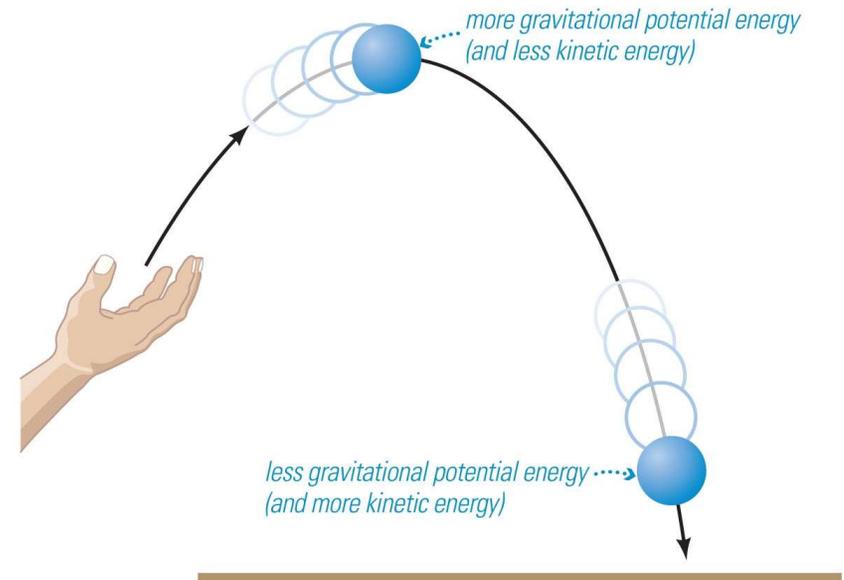

On Earth, it depends on...

- an object's mass ( $m$ ).
- the strength of gravity ( $g$ ).
- the distance an object could potentially fall.

E.g., Pendulum

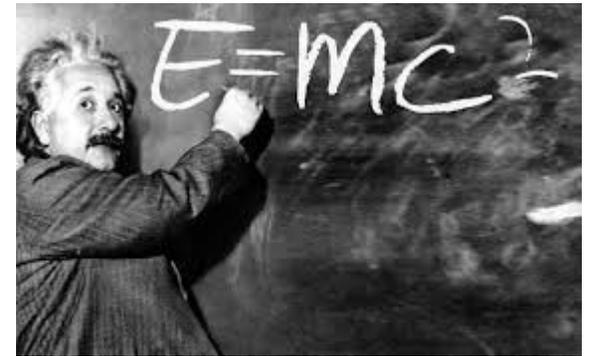

*The total energy (kinetic + potential) is the same at all points in the ball's flight.*

a The ball has more gravitational potential energy when it is high up than when it is near the ground.

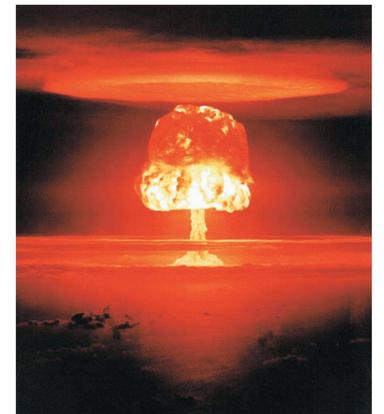

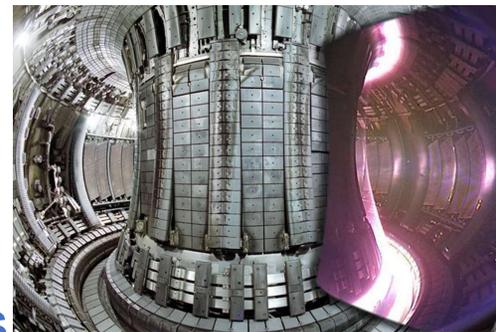

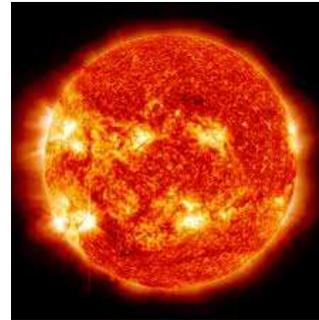

# The Relationship between Mass and Energy

- According to Einstein's famous equation, Mass itself is a form of potential energy.

$$E = mc^2$$

- A small amount of mass can release a great deal of energy.
  - Nuclear Fission power plant
  - Nuclear Fusion power plant
  - Nuclear Weapons (both)
  - Nuclear Fusion within Stars
- Concentrated energy can spontaneously turn into particles (for example, in particle accelerators).

# iClicker Question

**Question:** When a ball is dropped, some of the ball's energy changes from

- A. kinetic energy to gravitational potential energy
- B. gravitational potential energy to kinetic energy
- C. radiative energy to kinetic energy
- D. gravitational potential energy to radiative energy

# iClicker Question

**Question:** When a ball is dropped, some of the ball's energy changes from

- A. kinetic energy to gravitational potential energy
- B. gravitational potential energy to kinetic energy**
- C. radiative energy to kinetic energy
- D. gravitational potential energy to radiative energy

# Conservation of Angular Momentum

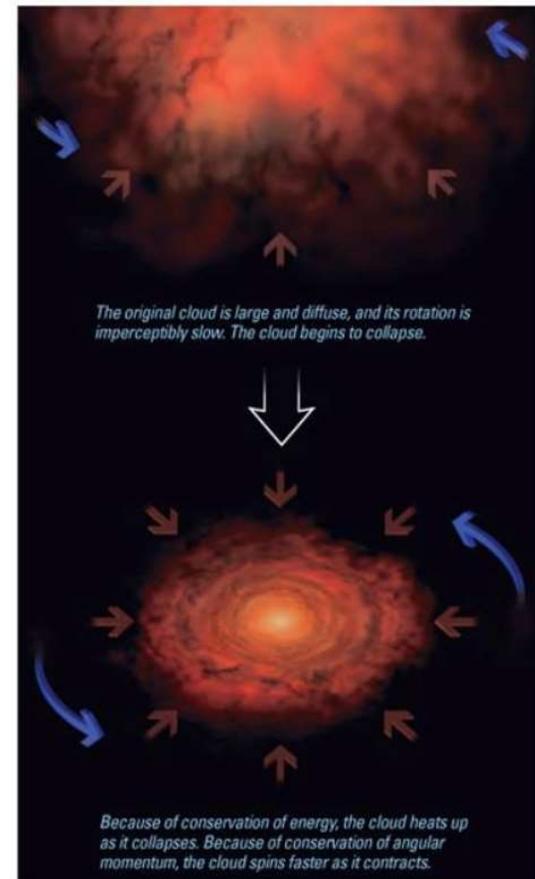

Orbital angular momentum = mass  $\times$  velocity  $\times$  radius

*In the product  $m \times v \times r$ , extended arms mean larger radius and smaller velocity of rotation.*

*Bringing in her arms decreases her radius and therefore increases her rotational velocity.*

**Example: Figure Skater**

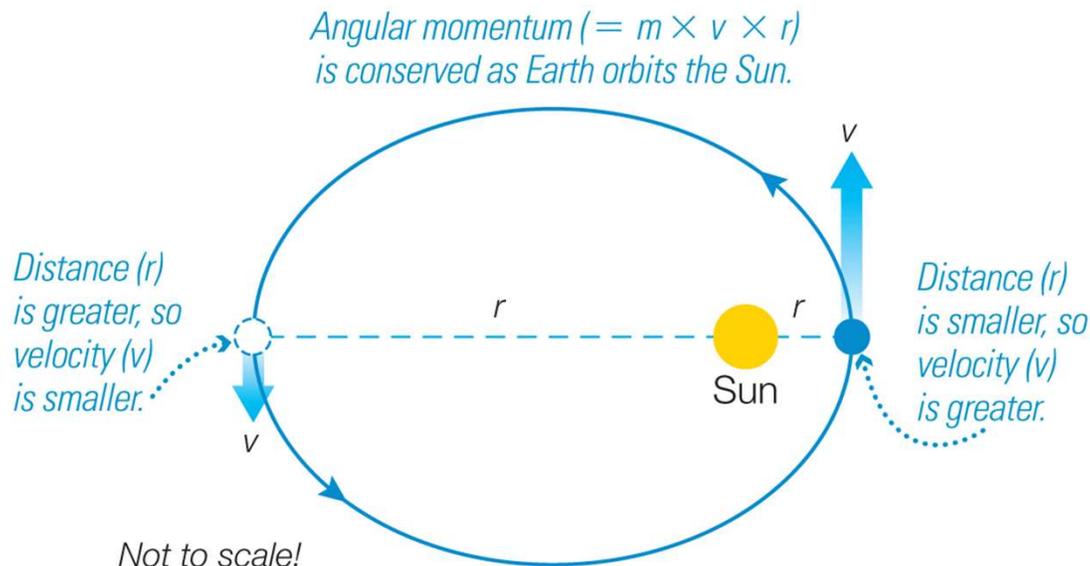

**Example: Solar System Formation**

# What is Orbital Angular Momentum?

Orbital angular momentum = mass  $\times$  velocity  $\times$  radius

How does this help explain Kepler's 2<sup>nd</sup> law?

**Angular momentum  
is conserved over the  
orbit**

↓ **in radius,**

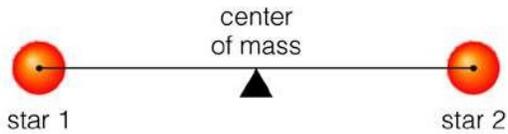

↑ **in velocity...**

**Because Earth's angular momentum at any point in its orbit depends on the product of its speed and orbital radius (distance from the Sun), Earth's orbital speed must be faster when it is nearer the Sun (and radius is smaller)**

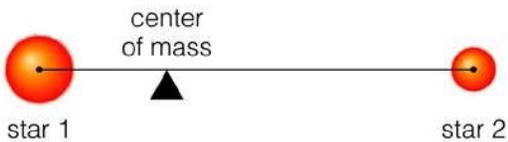

**Earth needs no fuel or push of any kind to keep orbiting the Sun – it will keep orbiting as long as nothing comes to take orbital momentum away**

# Center of Mass

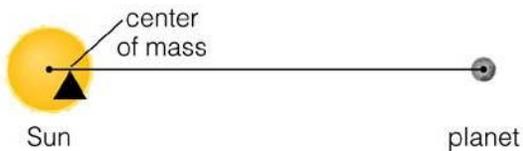

Two Stars of Equal Mass

Star 1 Is More Massive Than Star 2

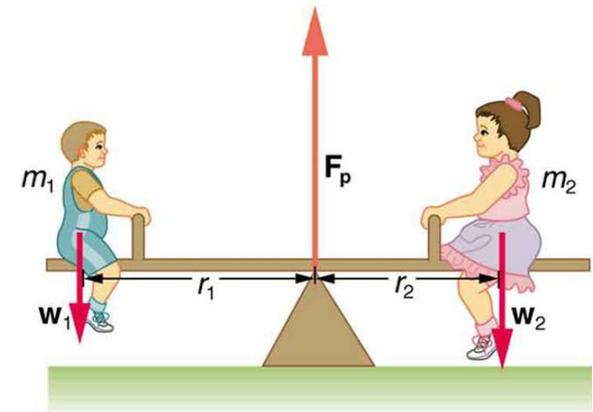

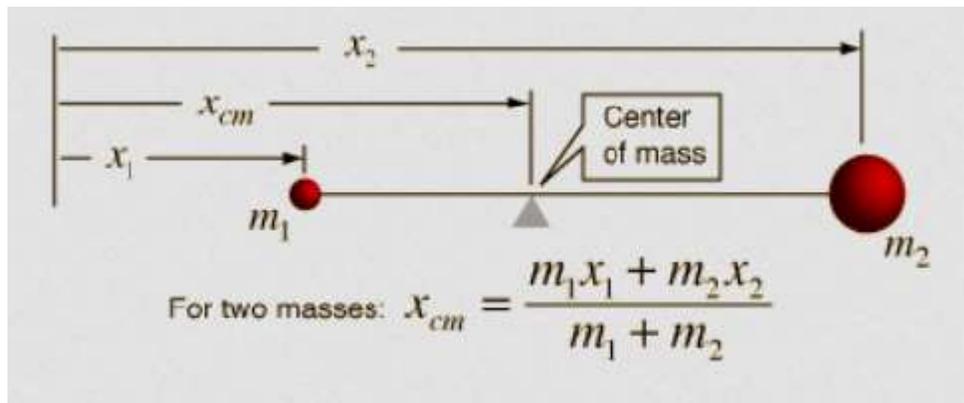

Sun Is Much More Massive Than Planet

tion, publishing as Addison Wesley.

**Objects attracted by gravity orbit around their center of mass**

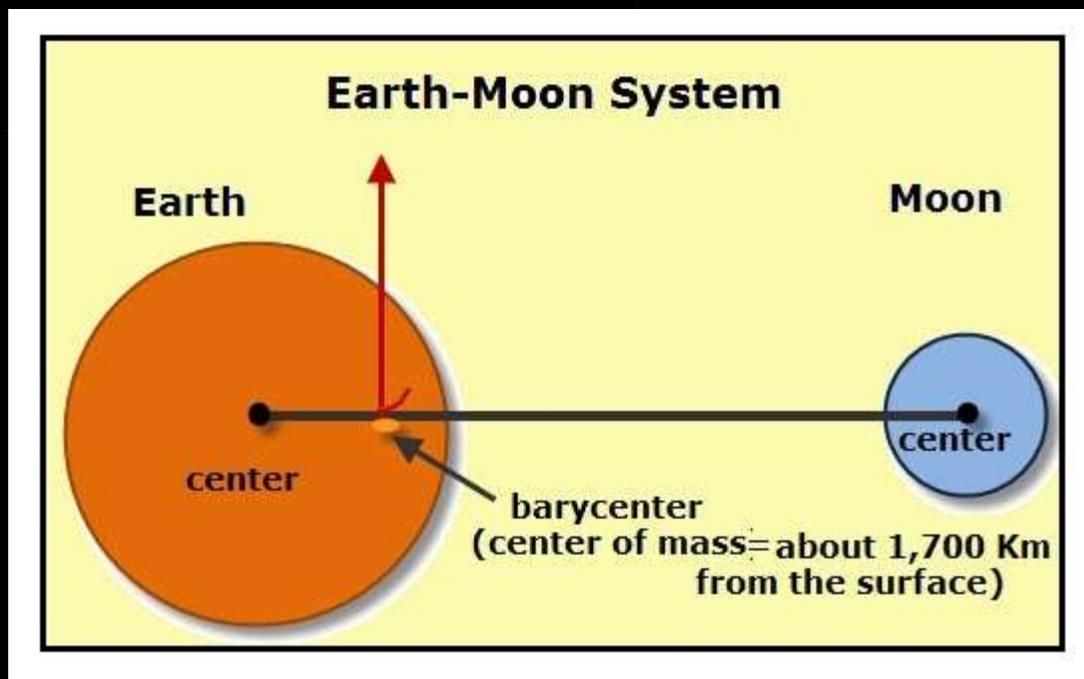

# Barycenters

A Barycenter is the center of mass of two or more bodies that are orbiting each other, which is the point around which they both orbit

*Jupiter doesn't orbit the Sun!*

*The Barycenter lies at 1.07 solar radii from the center of the Sun...*

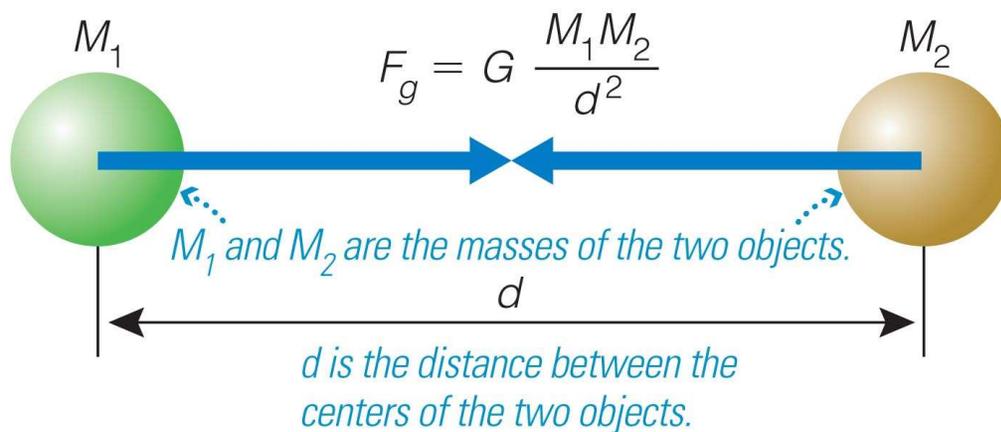

# What determines the strength of gravity?

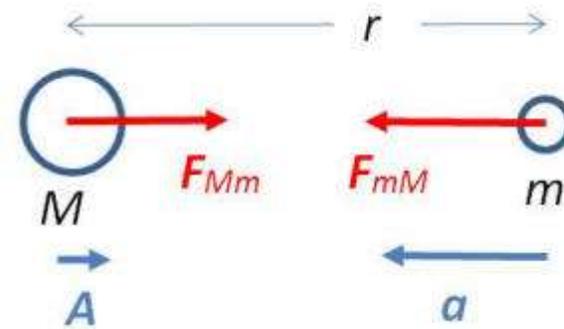

## The **Universal Law of Gravitation**:

1. Every mass attracts every other mass.
2. Attraction is *directly* proportional to the product of their masses.
3. Attraction is *inversely* proportional to the *square* of the distance between their centers.

The **universal law of gravitation** tells us the strength of the gravitational attraction between the two objects.

The Force between two objects must be the same

But the acceleration each experiences may be different ( $F=ma$ )

# iClicker Question

**Question:** Is the force (of gravity) that Earth exerts on you larger, smaller, or the same as the force you exert on it?

- A. Earth exerts a larger force on you.
- B. You exert a larger force on Earth.
- C. Earth and you exert equal and opposite forces on each other.

# iClicker Question

**Question:** Is the force (of gravity) that Earth exerts on you larger, smaller, or the same as the force you exert on it?

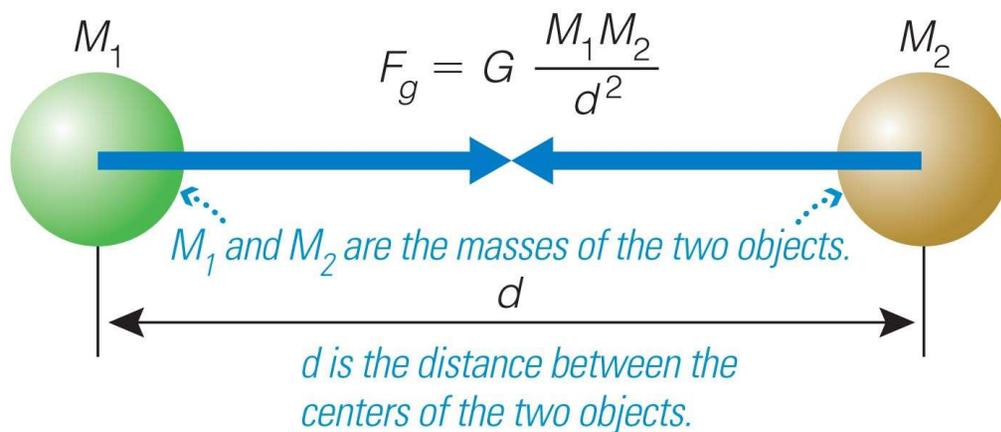

- A. Earth exerts a larger force on you.
- B. You exert a larger force on Earth.
- C. Earth and you exert equal and opposite forces on each other.**

# What determines the strength of gravity?

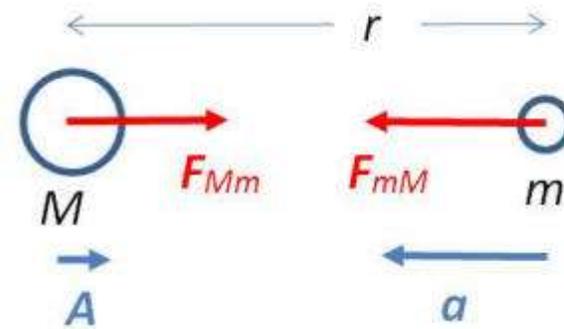

## The **Universal Law of Gravitation**:

1. Every mass attracts every other mass.
2. Attraction is *directly* proportional to the product of their masses.
3. Attraction is *inversely* proportional to the *square* of the distance between their centers.

The **universal law of gravitation** tells us the strength of the gravitational attraction between the two objects.

The Force between two objects must be the same

But the acceleration each experiences may be different ( $F=ma$ )

# Newton's Version of Kepler's 3<sup>rd</sup> Law

$$p^2 = \frac{4\pi^2}{G(M_1 + M_2)} a^3$$

$p$  = orbital period, in seconds

$a$  = average orbital distance (between centers), in meters

$(M_1 + M_2)$  = sum of object masses, in kg

$G$  is the gravitational constant,  $6.67 \times 10^{-11} \frac{m^3}{kg \times s^2}$

**Example:** Use the fact that Earth orbits the Sun at an average distance of 1 AU over the period of 1 year to calculate the Sun's mass.

$$p_{Earth}^2 = \frac{4\pi^2}{G(M_{Sun} + M_{Earth})} a_{Earth}^3$$

$$M_{Sun} + M_{Earth} \sim M_{Sun} (> 3 \times 10^6 M_{Earth})$$

$$1 \text{ AU} = 1.5 \times 10^{11} \text{ m}$$

$$1 \text{ year} = 3.15 \times 10^7 \text{ seconds}$$

**Substitute:**

$$p_{Earth}^2 \sim \frac{4\pi^2}{G \times M_{Sun}} a_{Earth}^3$$

**Rearrange:**

$$M_{Sun} \sim \frac{4\pi^2}{G \times p_{Earth}^2} a_{Earth}^3$$

**Evaluate:**

$$M_{Sun} \sim \frac{4\pi^2}{\left(6.67 \times 10^{-11} \frac{m^3}{kg \times s^2}\right) \times (3.15 \times 10^7 \text{ s})^2} \times (1.5 \times 10^{11} \text{ m})^3 \sim 2.0 \times 10^{30} \text{ kg}$$

# Newton's version of Kepler's third law & Orbits

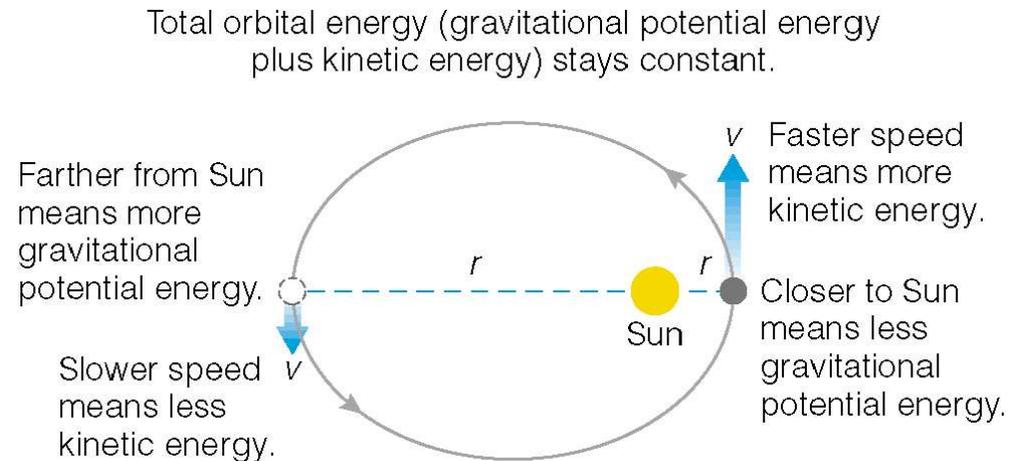

*If a small object orbits a larger one and you measure the orbiting object's orbital period AND average orbital distance THEN you can calculate the mass of the larger object.*

## Examples:

- Calculate the mass of the Sun from Earth's orbital period and average distance.
- Calculate the mass of Earth from orbital period and distance of a satellite.
- Calculate the mass of Jupiter from orbital period and distance of one of its moons.

## What else can we learn from Conservation Laws?

- Orbits **cannot** change spontaneously (*would orbit continuously*)
- An object's orbit can only change if it somehow gains or loses orbital energy =  
kinetic energy + gravitational potential energy

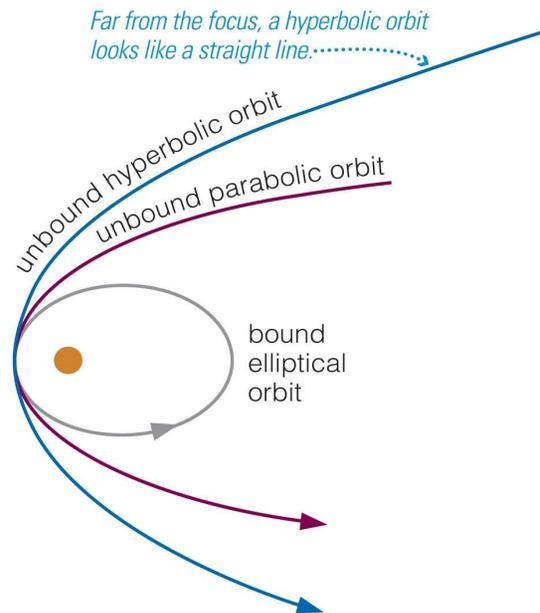

# How does Newton's law of gravity extend Kepler's laws?

Kepler's first two laws apply to all orbiting objects, not just planets.

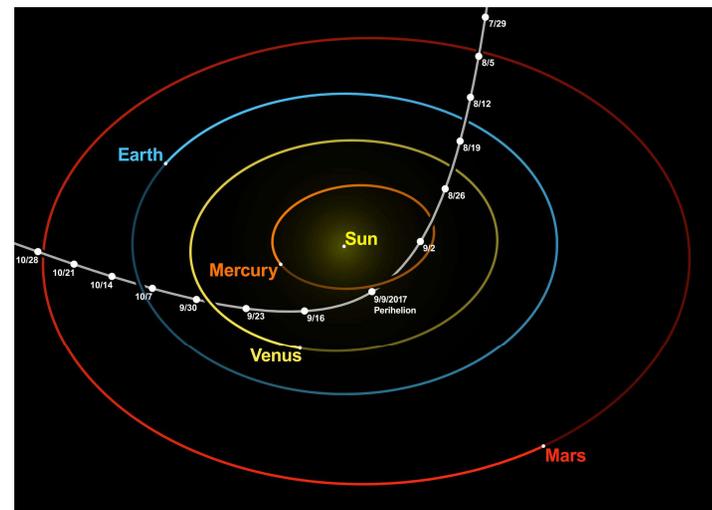

Ellipses are not the only orbital paths. Orbits can be:

- bound orbits (ellipses)
- Unbound orbits
  - parabola
  - hyperbola

## An Interstellar Visitor:

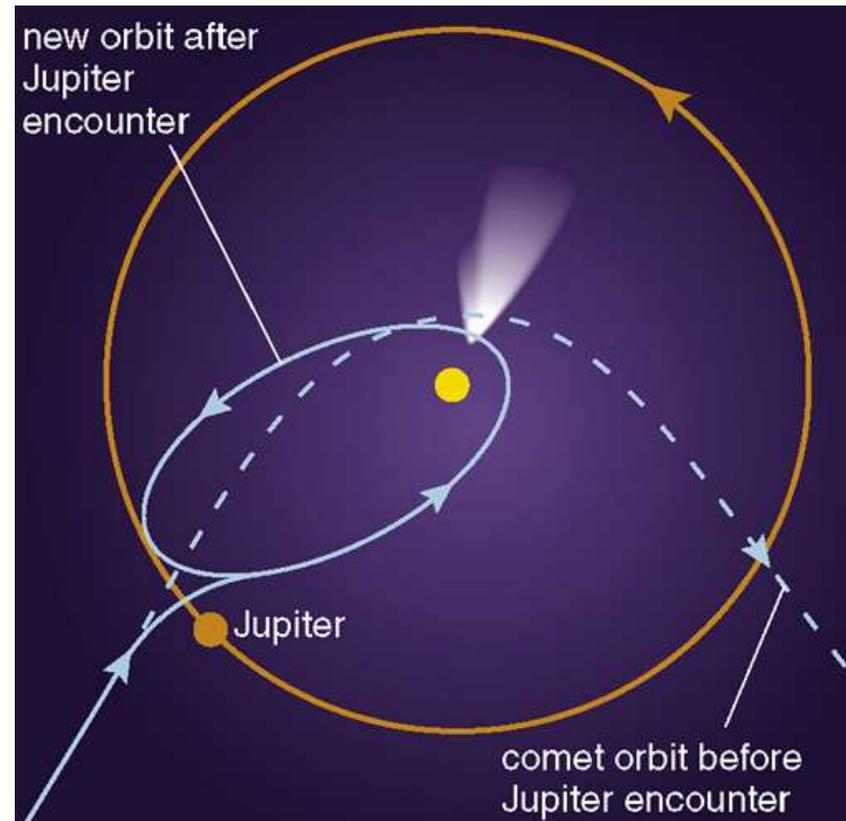

- 'Oumuamua was found on an unbound hyperbolic trajectory on 19<sup>th</sup> Oct 2017 (*it will not return to our Solar System*)

# How Can you Change the Orbital Energy (or Path of an Object?)

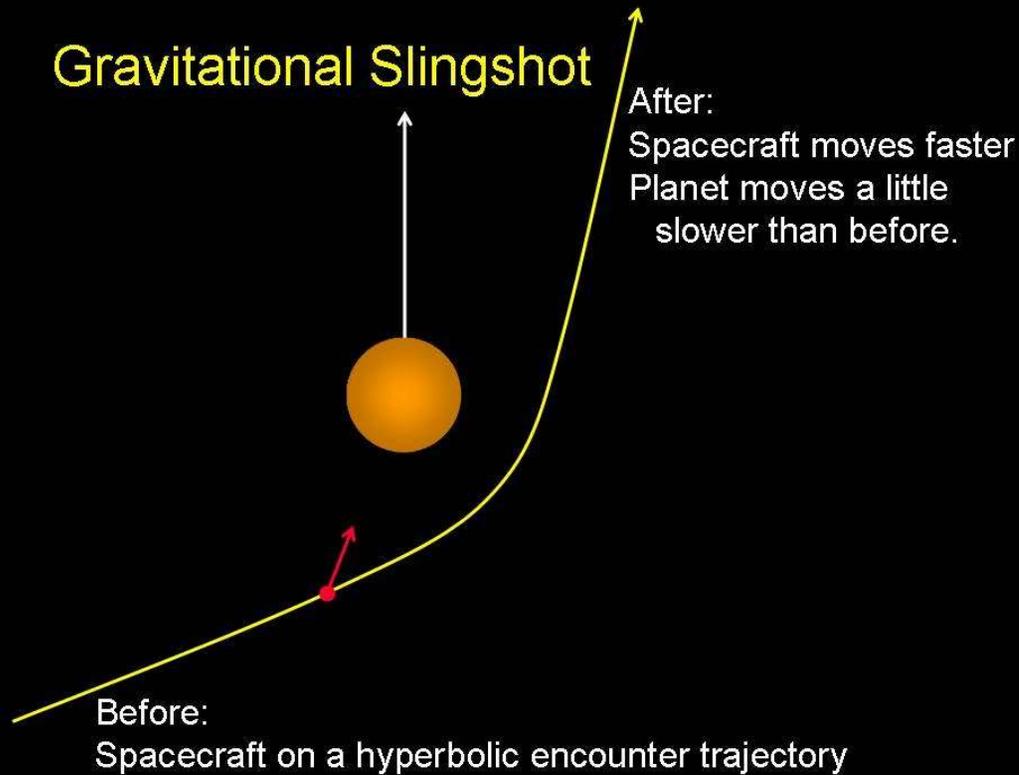

⇒ So what can make an object gain or lose orbital energy?

- Friction or atmospheric drag (satellites crashing)
- A gravitational encounter (e.g., with Jupiter)
  - Can help explain some captured moon (e.g., Triton at Neptune, Phobos/Deimos at Mars)
- Rockets.... By applying what is commonly known as 'delta-V' or  $\Delta V$

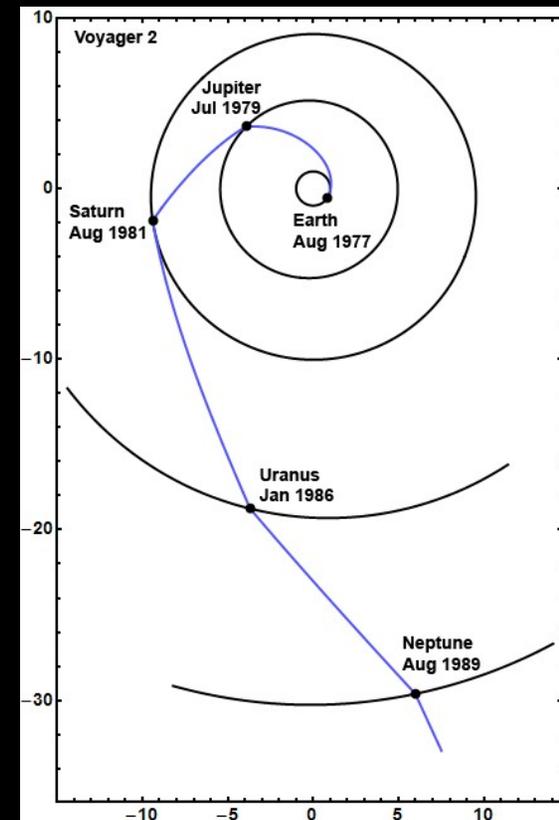

# The Charm of Gravity Assists...

## Gravitational Slingshot

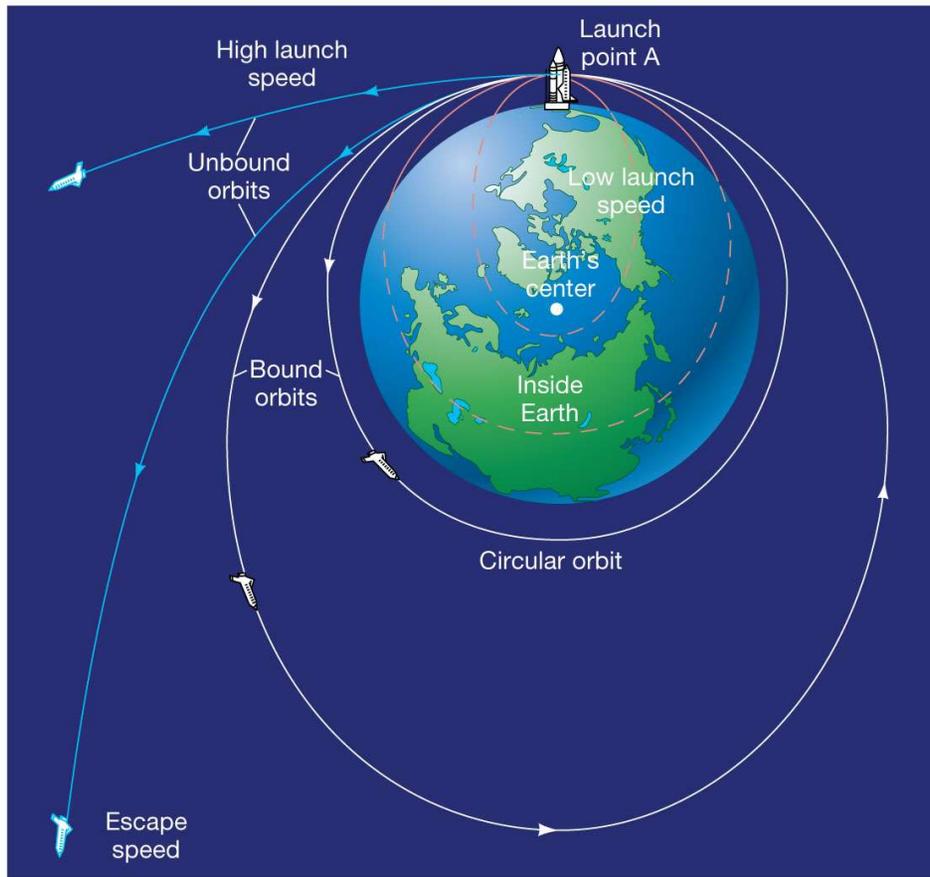

**Voyager 2 used gravitational slingshots at Jupiter, Saturn and Uranus to get to Neptune**

# What is Escape Velocity?

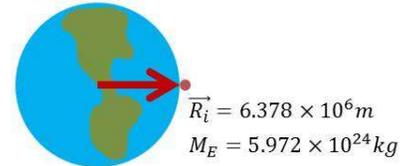

**Minimum velocity needed to break orbit – independent of mass – for Earth it is 11.2 km/s**

© 2011 Pearson Education, Inc.

## Example 2 – Escape Velocity

Let's use the concept of gravitational potential energy and work out another classic problem: What initial velocity is required in order for the object to leave the Earth's orbit.

Using conservation of energy we know that:

$$K_i + U_i = K_f + U_f$$

$$K_i + U_i = U_f$$

We also know that the potential energy due to gravity takes the form:

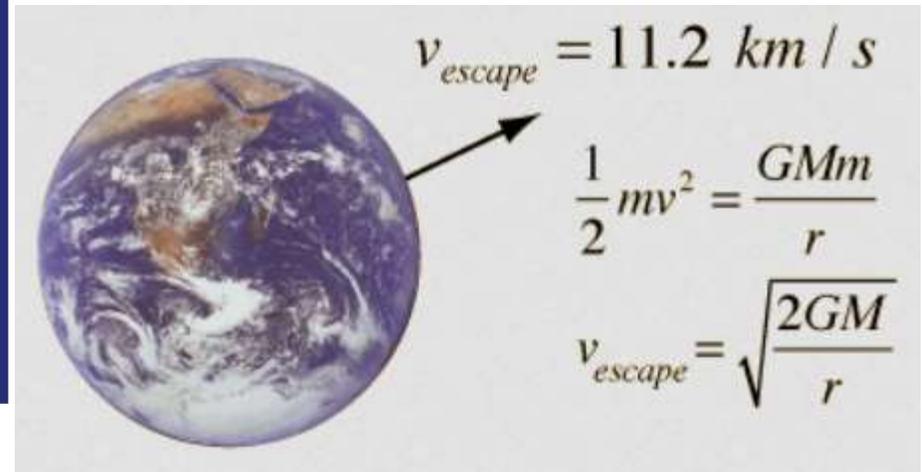

$$U_{gravity} = -\frac{Gm_1M_2}{R}$$

Substituting everything in:

$$\frac{1}{2}m_1v_i^2 - \frac{Gm_1M_E}{R_i} = -\frac{Gm_1M_E}{R_f}$$

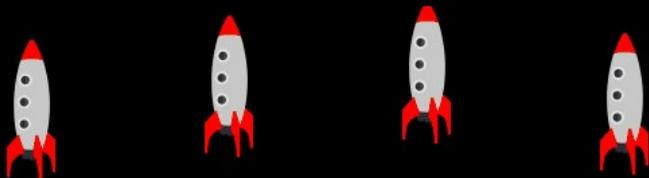

$R_f = \infty$  when the object has escaped the Earth's gravity.

$$\frac{1}{2}m_1v_i^2 = -\frac{Gm_1M_E}{\infty} + \frac{Gm_1M_E}{R_i}$$

## How fast a rocket would have to go to leave every planet

Rockets are Mostly (90%) Fuel!

**Mercury**  
9,507 mph

**Venus**  
23,175 mph

**Earth**  
25,031 mph

**Mars**  
11,252 mph

**Jupiter**  
134,664 mph

**Saturn**  
80,731 mph

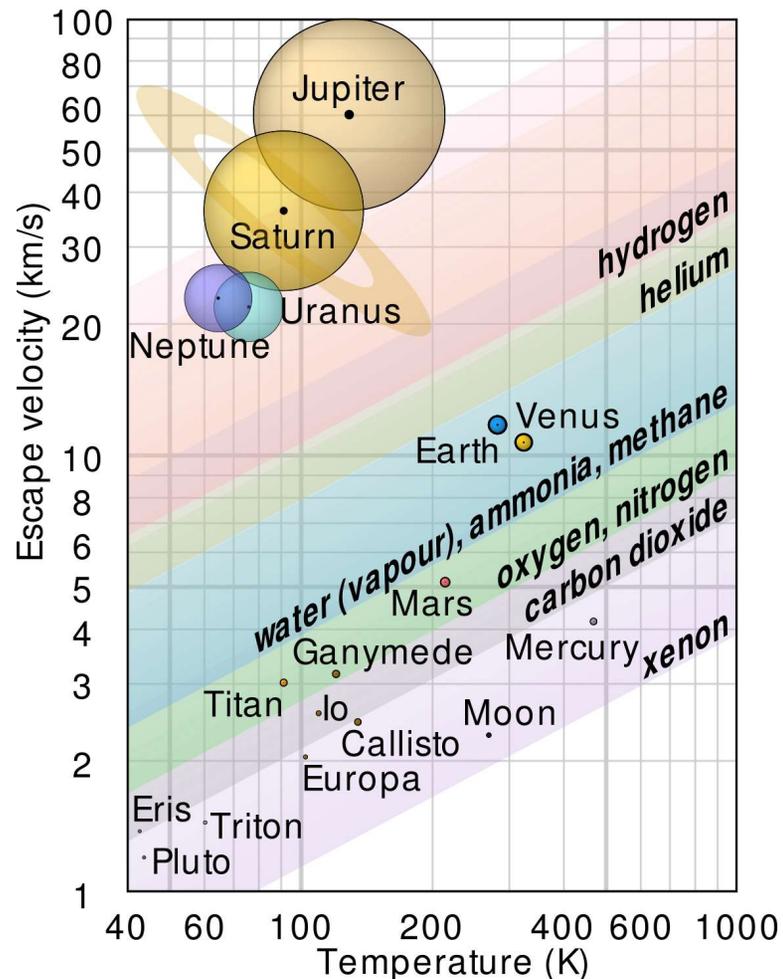

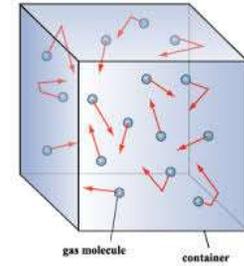

**Uranus**  
47,826 mph

**Neptune**  
52,702 mph

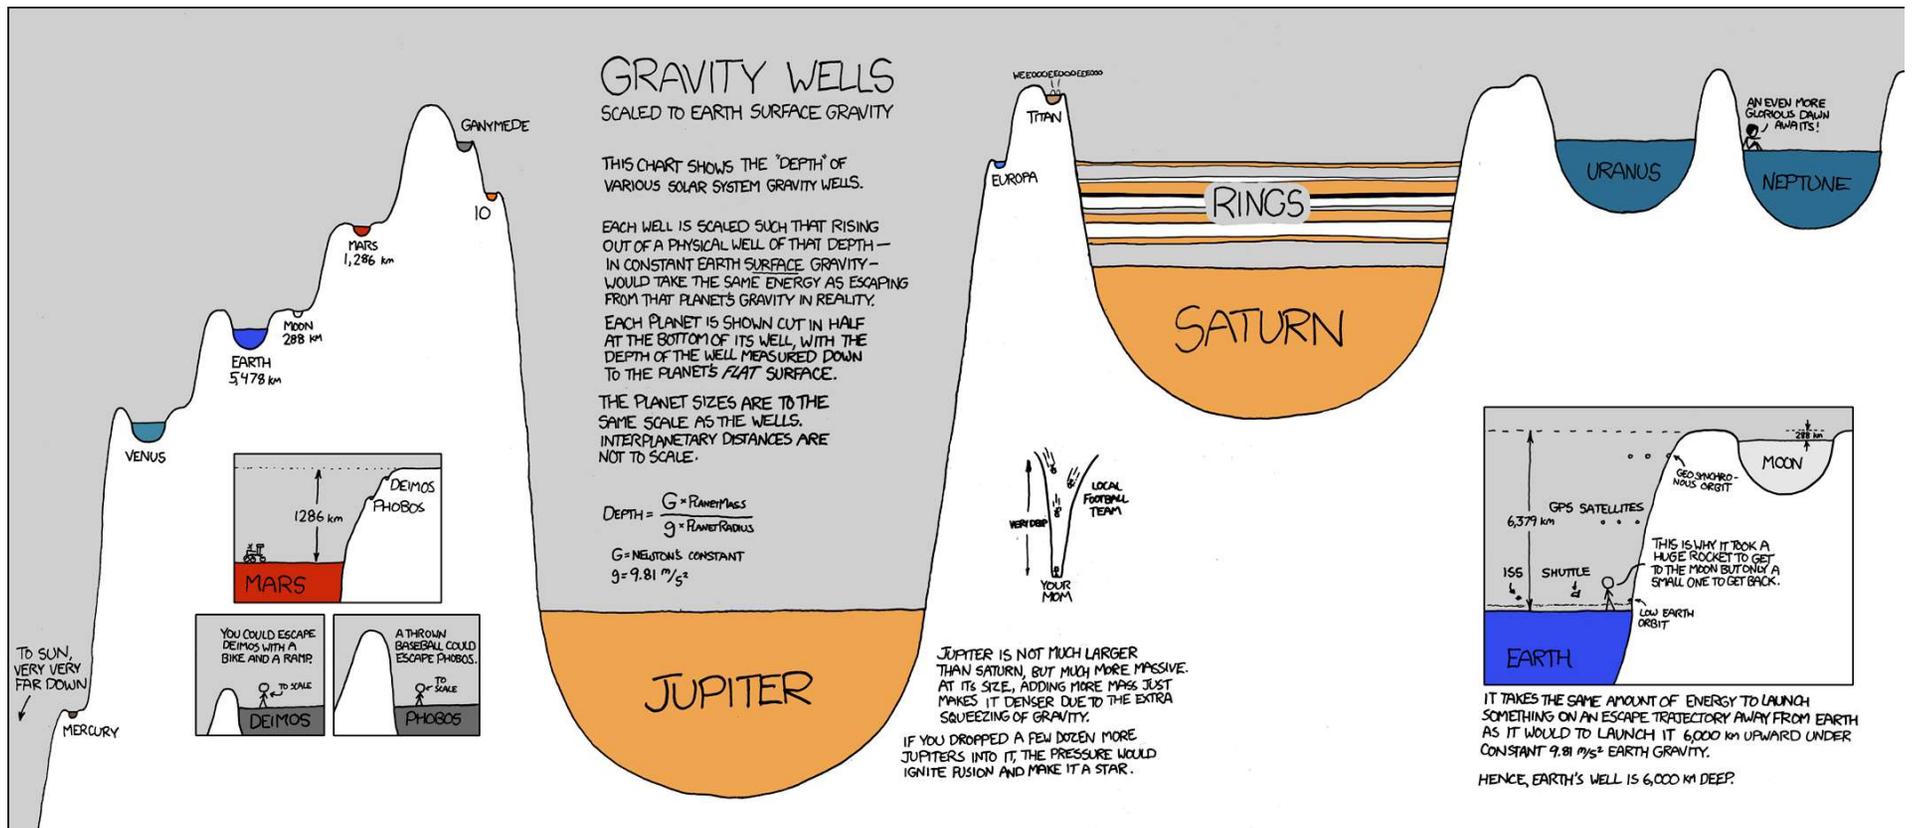

# Escape Velocity and Thermal Energy

- Kinetic Energy =  $\frac{1}{2} mv^2$
- For the same temperature, lighter atoms have more kinetic energy.
- A higher fraction will have sufficient velocity to escape the planets gravity for smaller atoms, and/or higher temperatures.

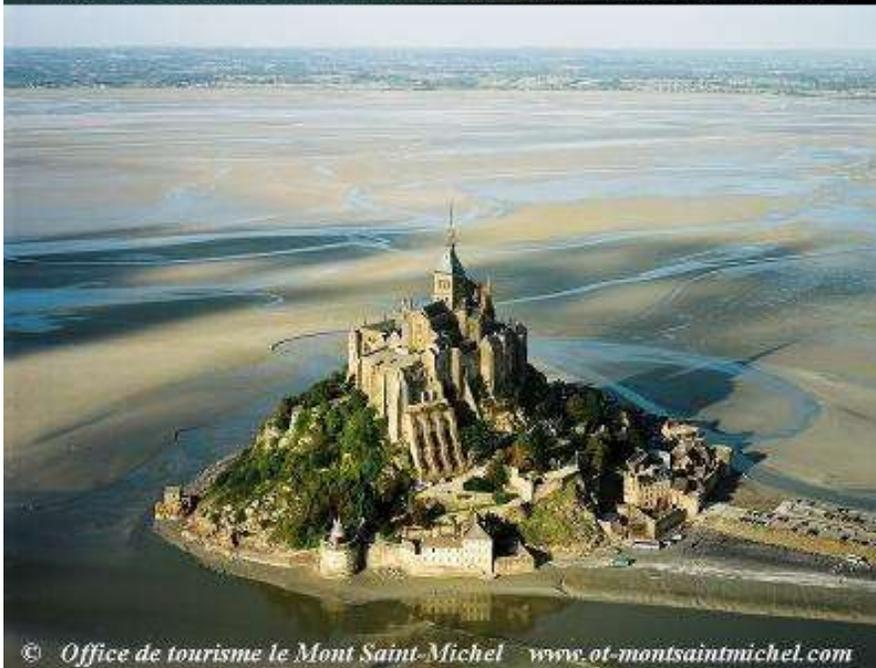

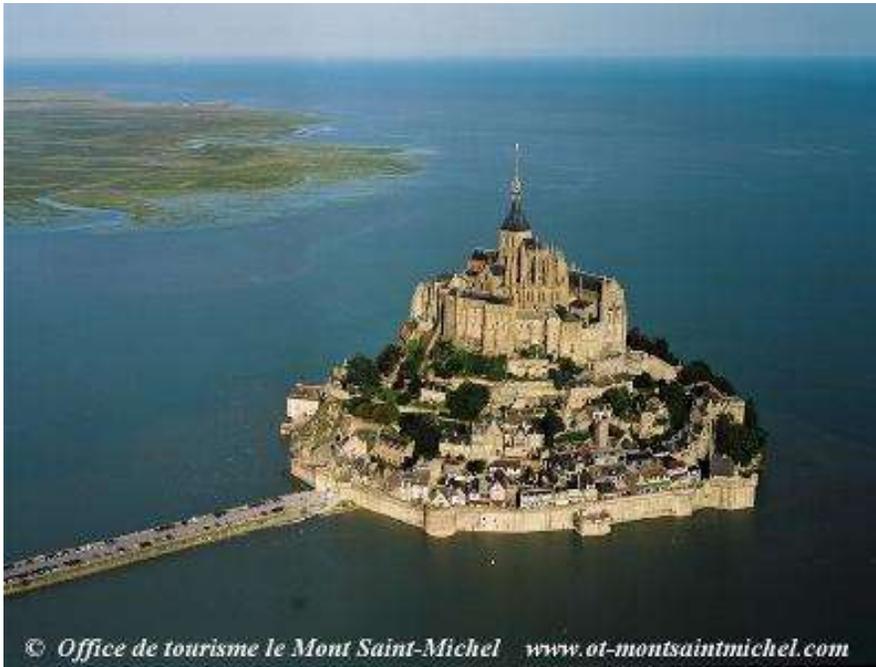

# Gravity Wells (Not Tested Material)

<https://xkcd.com/681/>

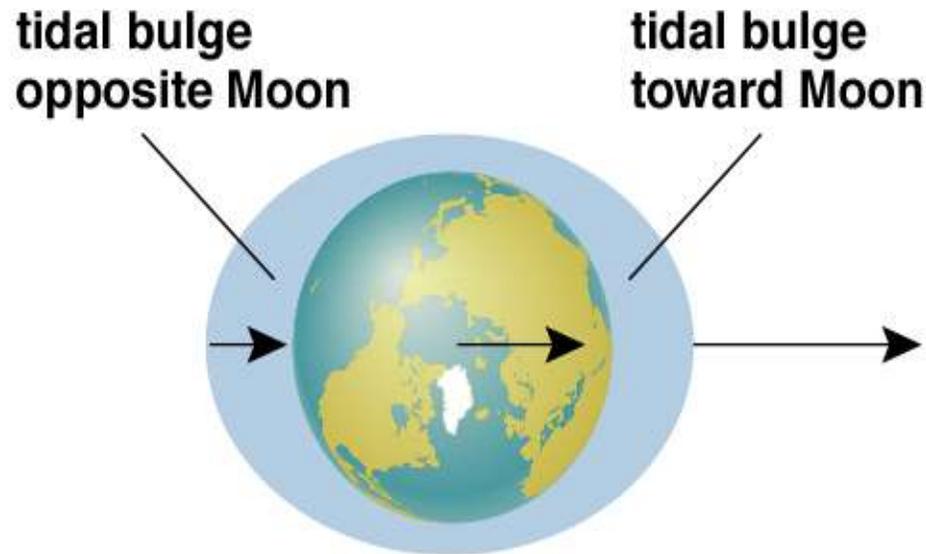

# Tides

- **Every place on Earth passes through high tides twice per day as the Earth rotates.**
- **High tides occur every 12 hours 25 minutes**
  - **remember, the Moon moves!**
- **The Sun's tidal effect on Earth is not as strong. Remember the inverse square law....the Sun is a long way away.**

# Tides

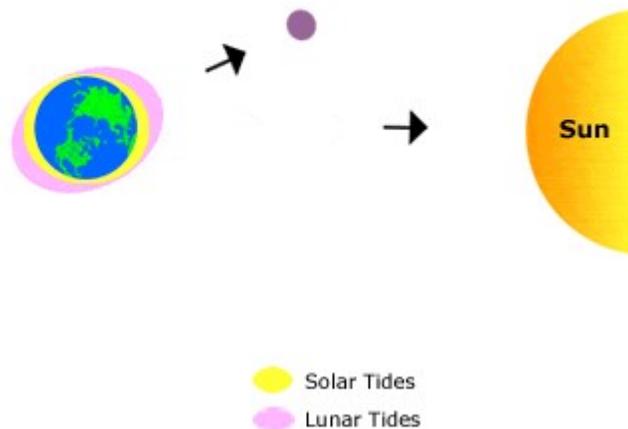

*Not to scale!* The real tidal bulge raises the oceans by only about 2 meters.

Copyright © Addison Wesley

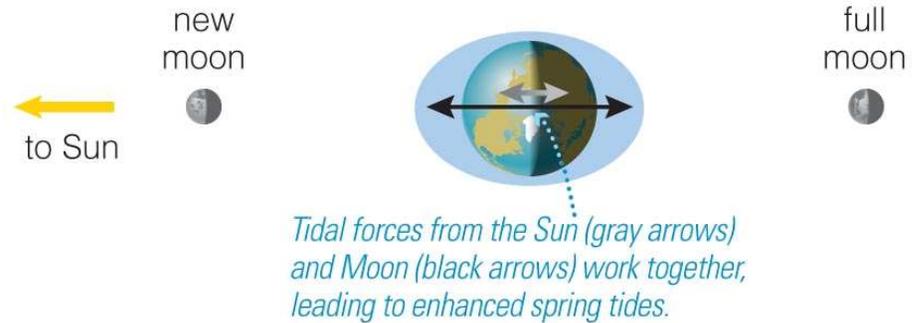

- **Gravitational force decreases with (distance)<sup>2</sup>**
  - The Moon's pull on Earth is strongest on the side facing the Moon, and weakest on the opposite side.
- **The Earth gets stretched along the Earth-Moon line.**
- **The oceans rise relative to land at these points.**

# Tides and Phases

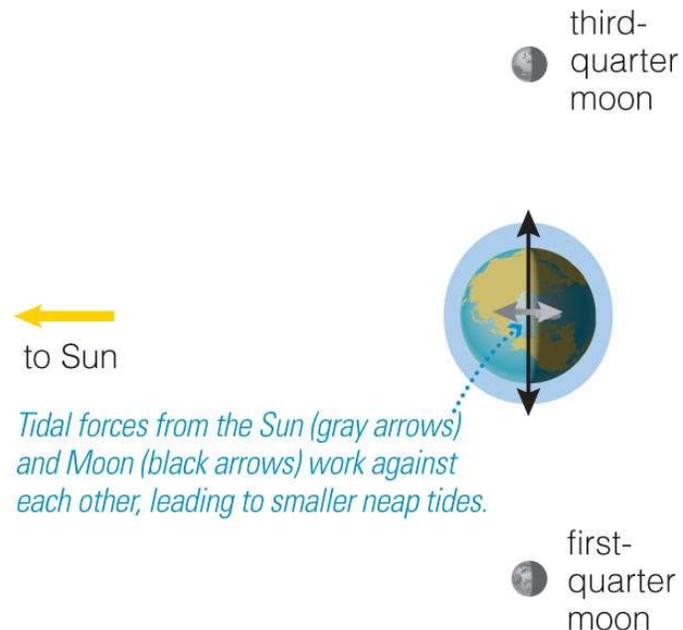

**Size of tides depends on the phase (relative position) of the Moon.**

**Spring tides** occur at new moon and full moon:

**Neap tides** occur at first- and third-quarter moon:
