

Hyperdog. Trace gas sniffer.

Robert E. Peale

Andrei Muraviev, Doug Maukonen,
Chris Fredricksen, Gautam Medhi

Can an instrument compete with a dog in speed, sensitivity, and accuracy of trace gas detection?

- Explosives
- Drugs
- Medical diagnostics
- Forensics
- Land mines
- Process monitoring
- Rescue
- Atmospheric science
- Planetary probes

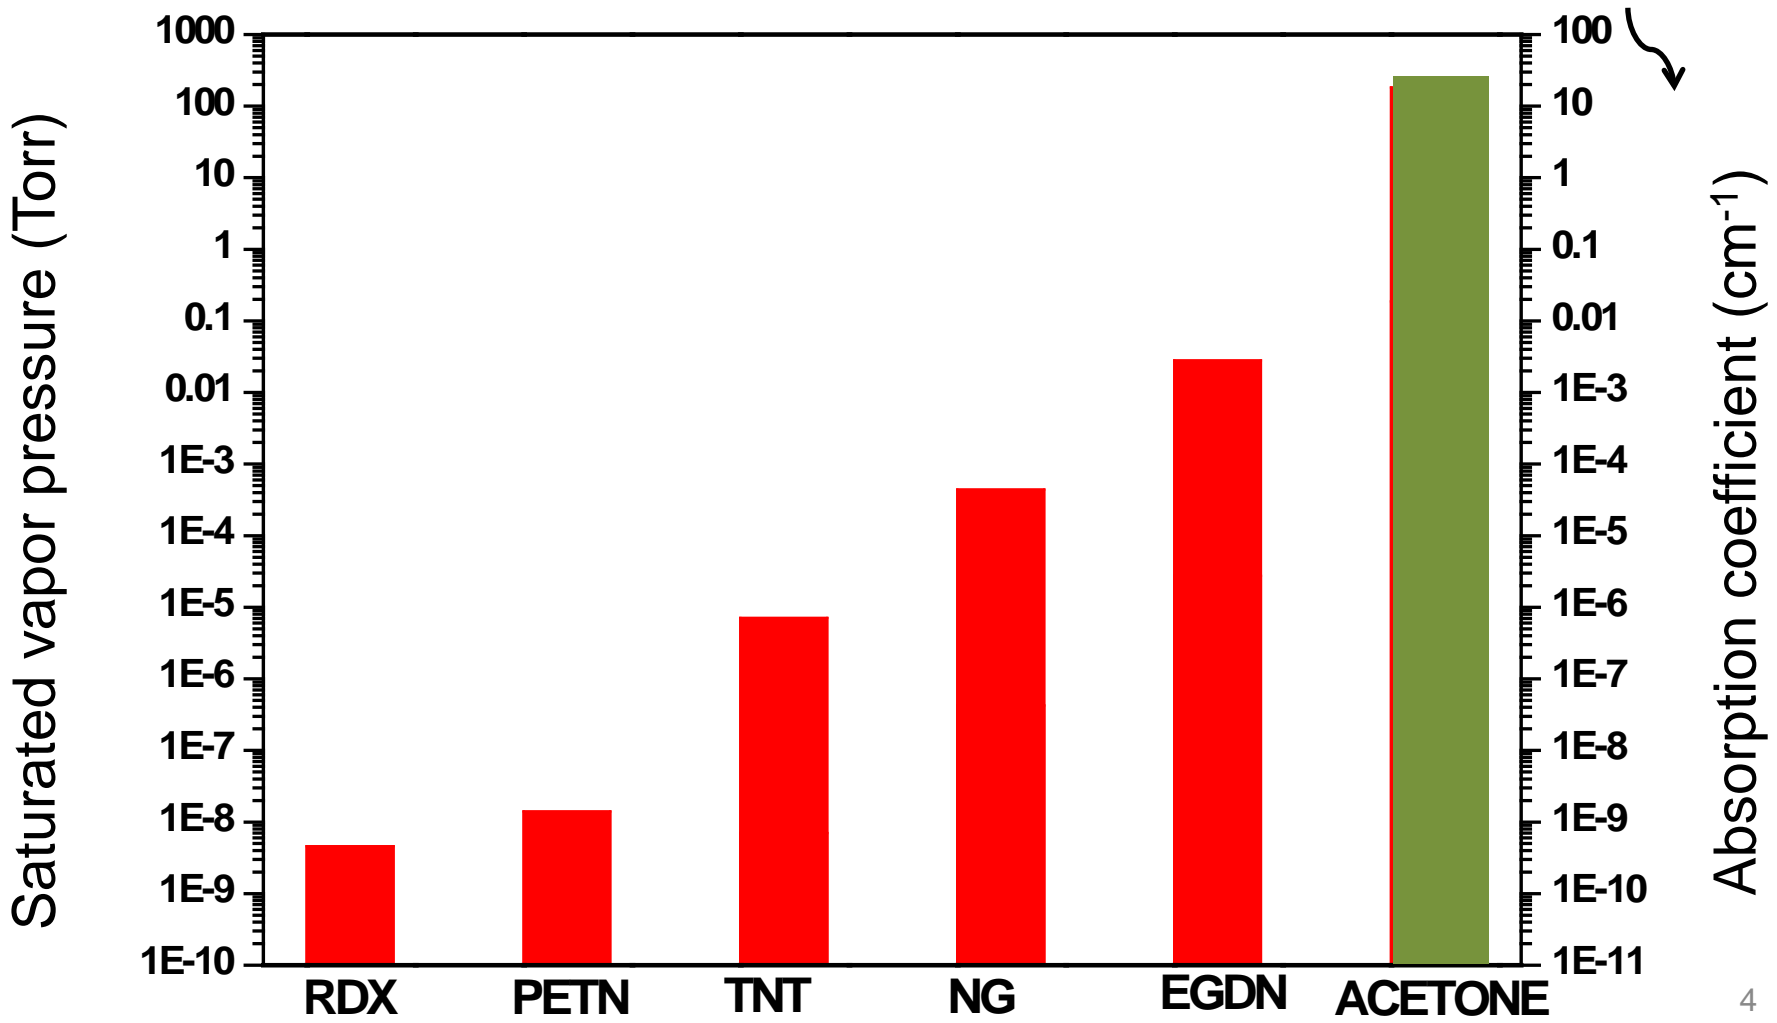

For speed and chemical specificity, we
focus on infrared spectral sensing

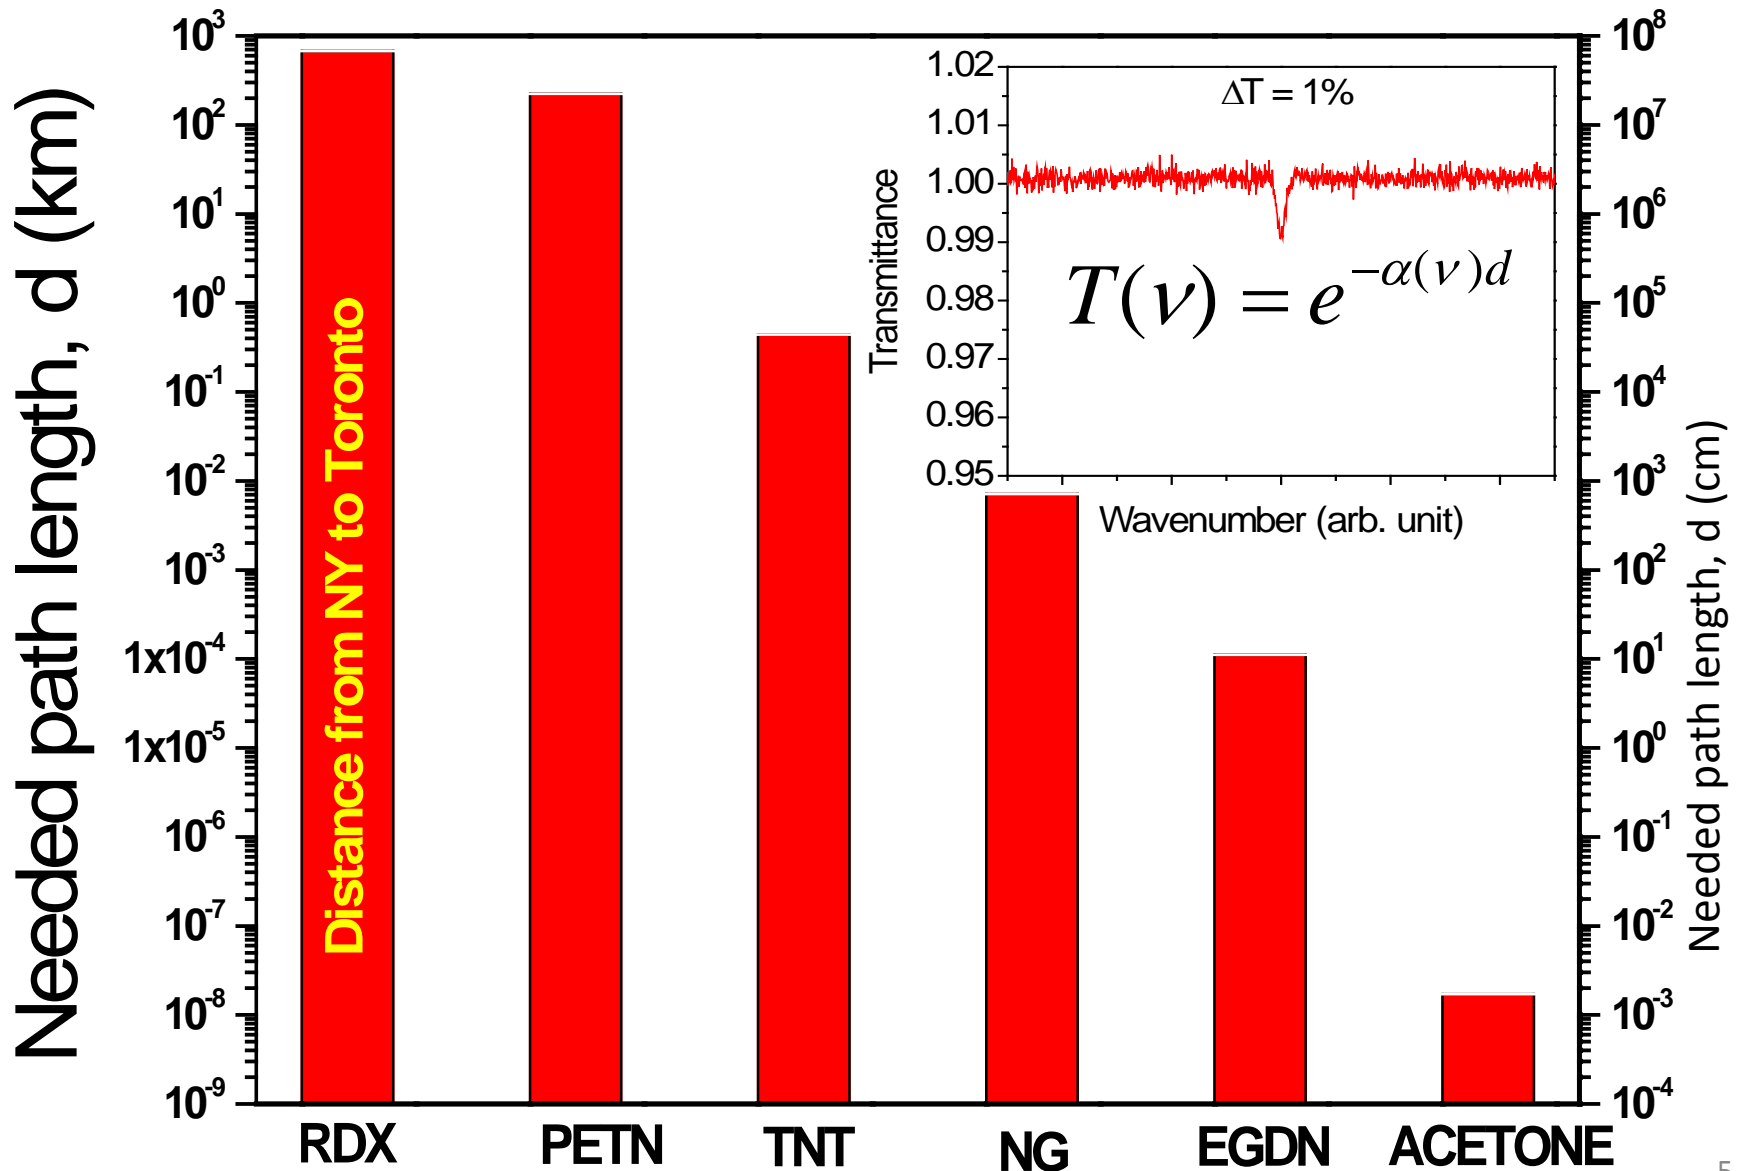

What about sensitivity?

Example: Explosives have very low vapor pressures and absorption coefficients

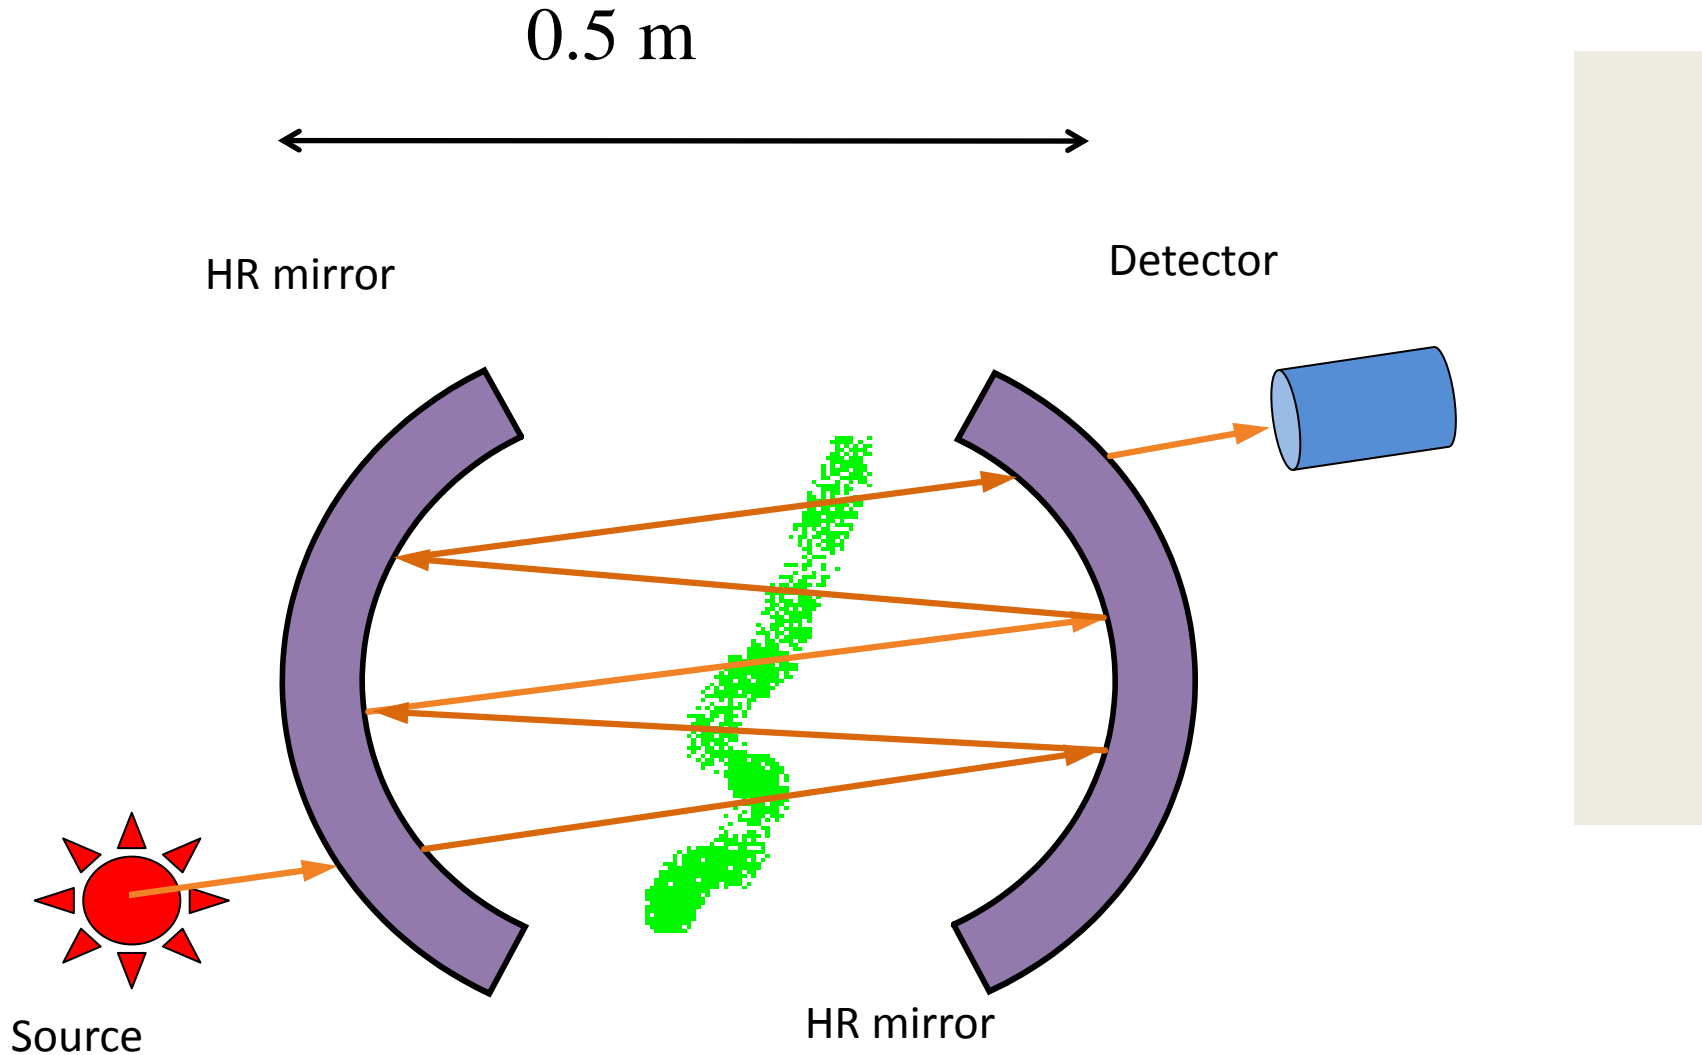

For molecular cross section $\sim 10^{-18} \text{ cm}^2$

Long optical path lengths needed to detect explosives

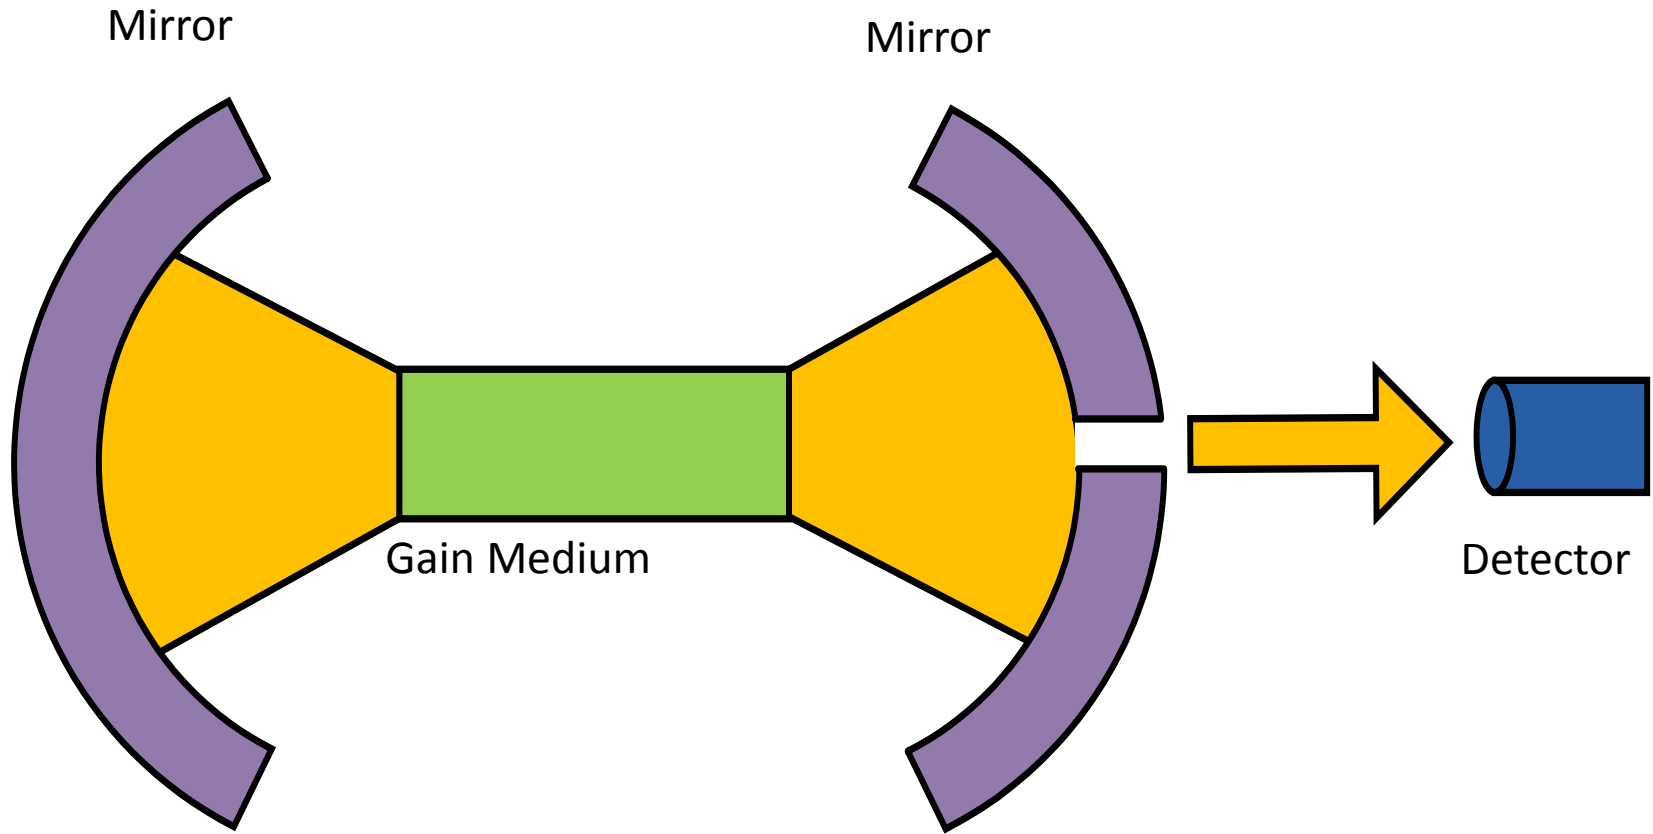

Long paths need to be folded, e.g. White cell

Passive cavities provide insufficient path length for detecting explosives

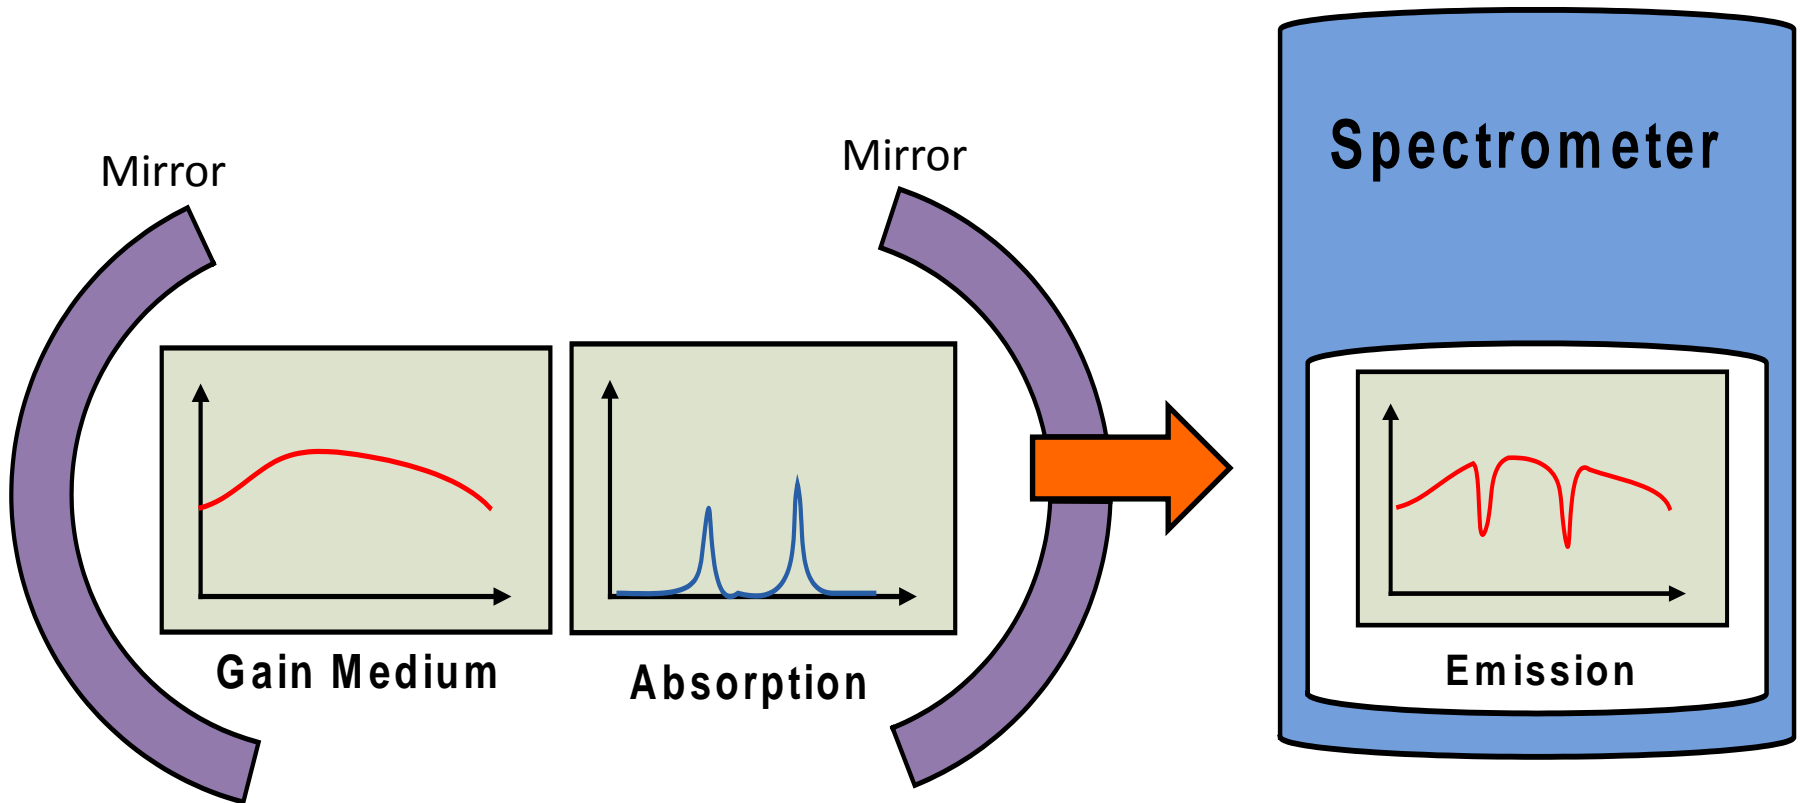

Opportunity: Active cavity can give sufficient path length

Effective path length for physical 35 cm path
can exceed 1 kilometer

Basis of Hyperdog: Intracavity Laser Absorption Spectroscopy

Key Enablers are...

1. External Cavity Mid-IR Quantum Cascade Laser
2. Scanning Fabry-Perot Spectrometer
3. Control and acquisition electronics

QCL

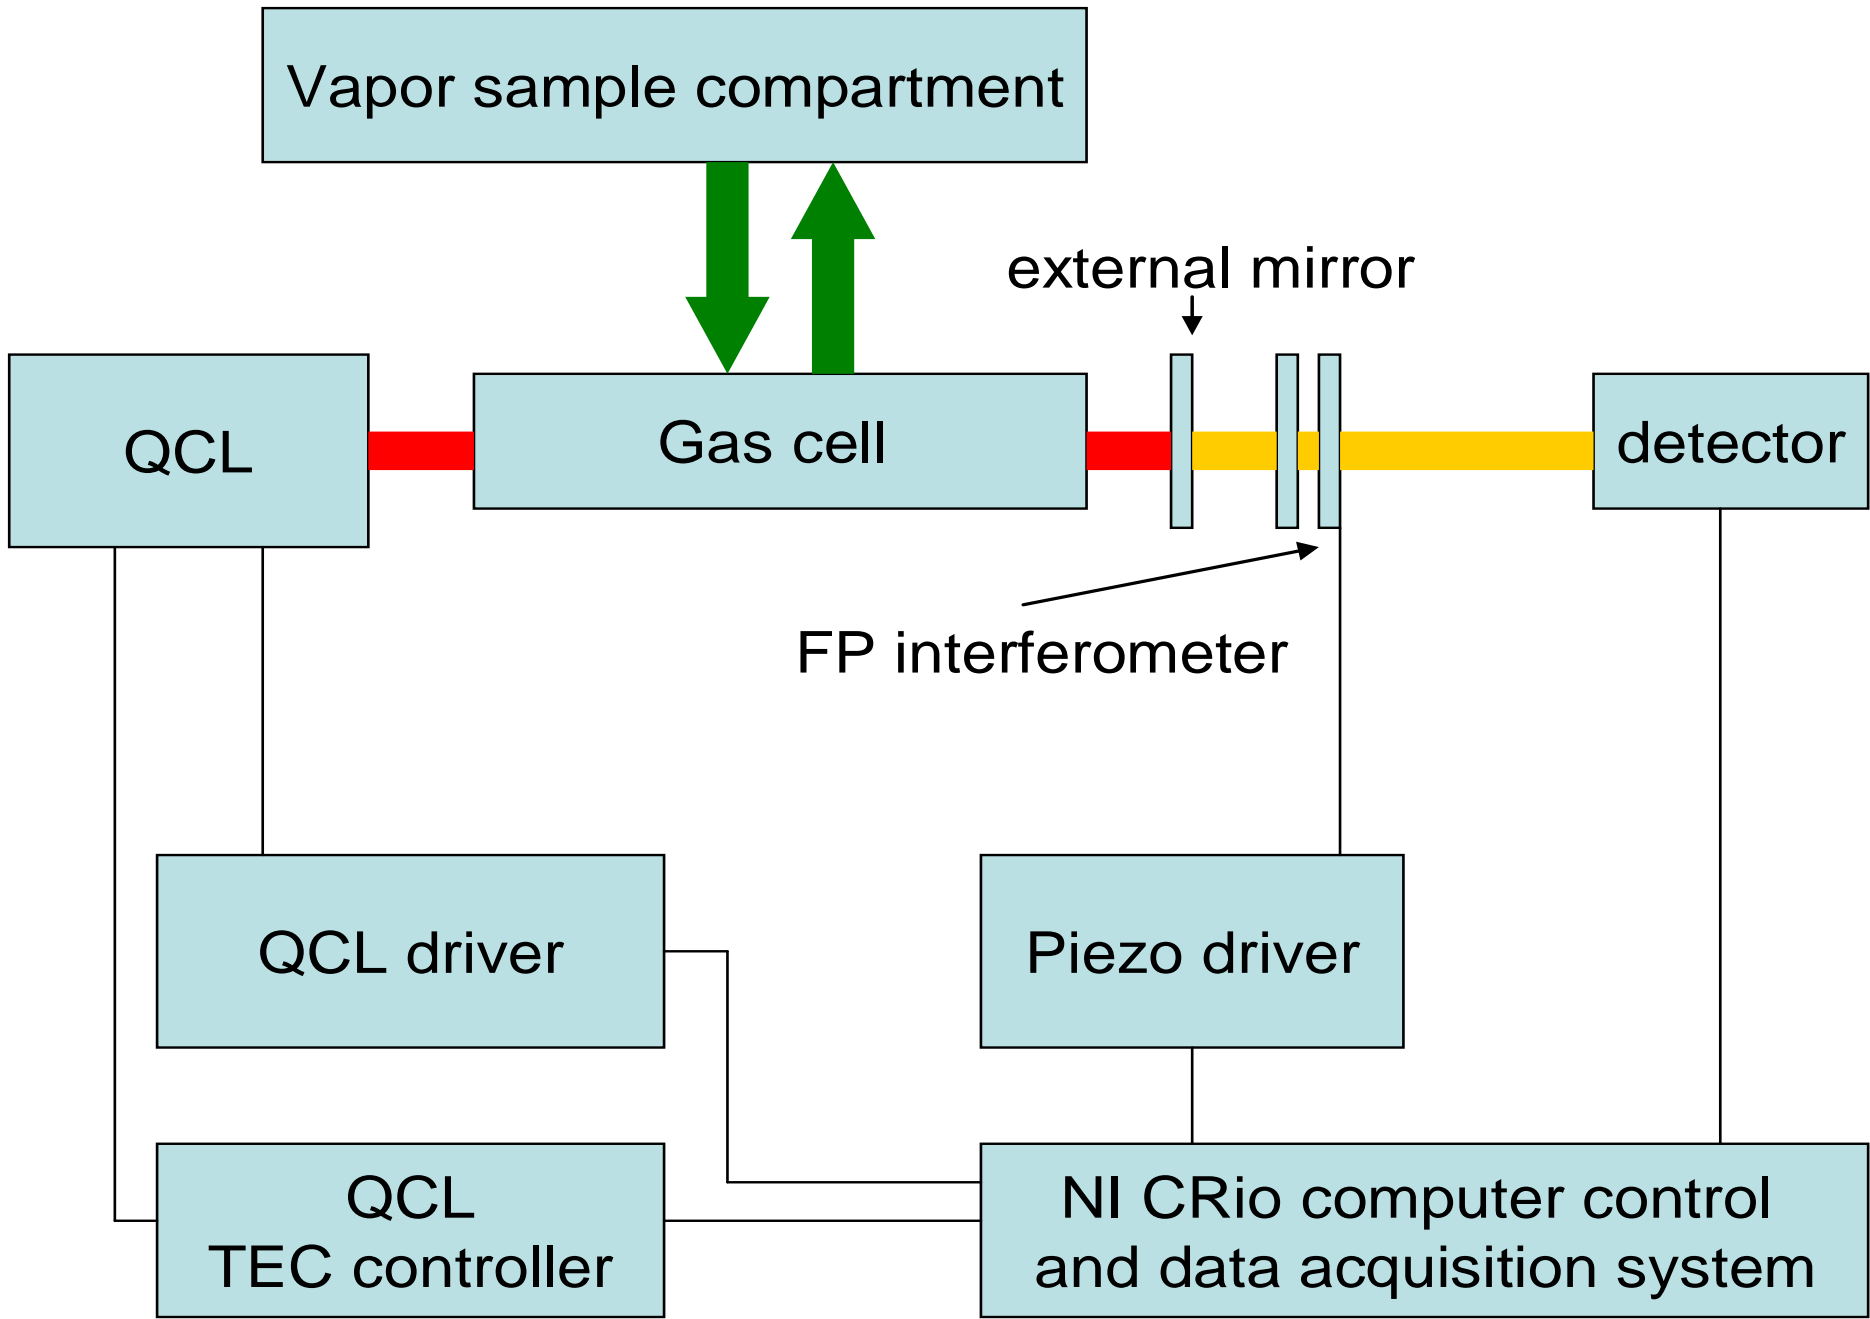

Emission spectrum of multimode QCL

60 cm^{-1} wide spectrum

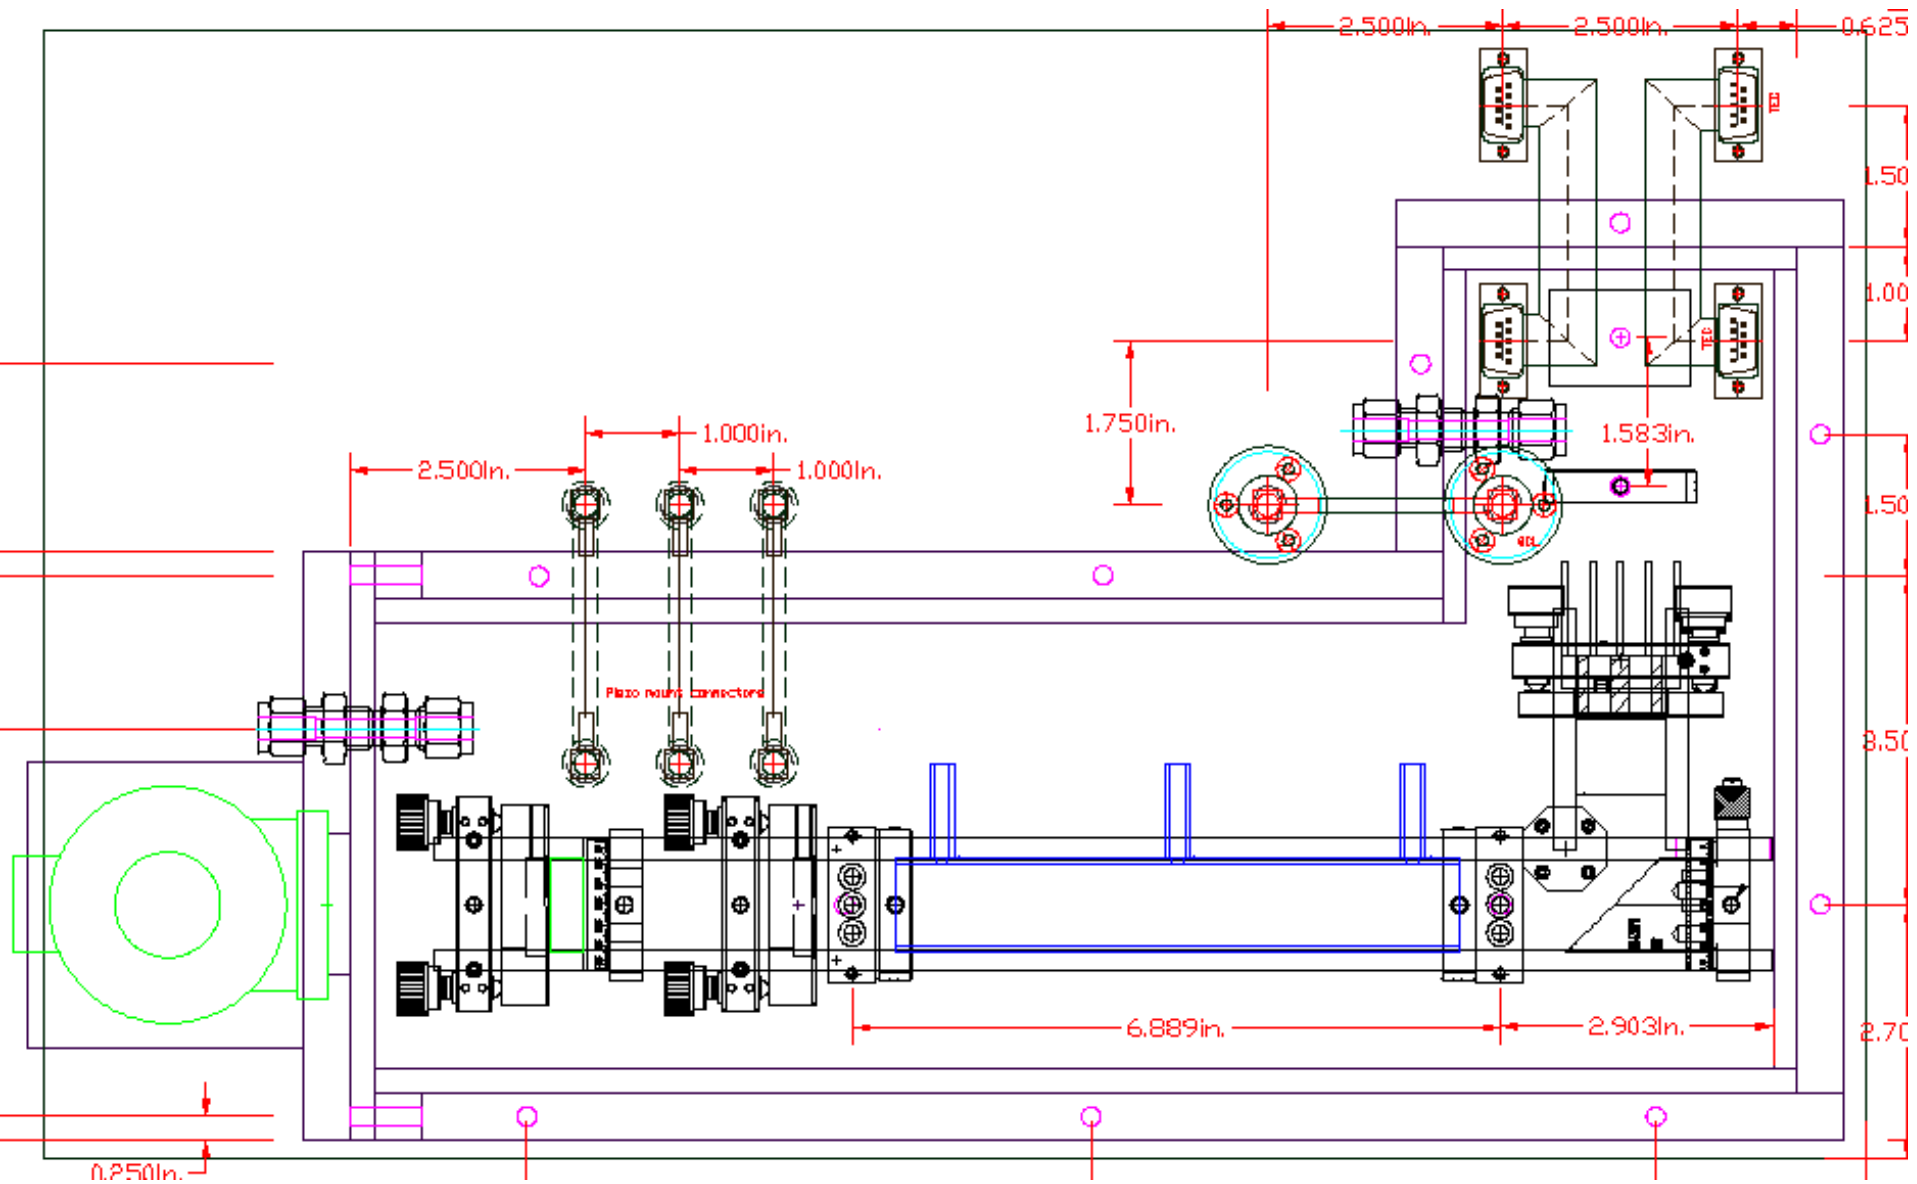

Hyperdog is an intracavity laser absorption spectrometer

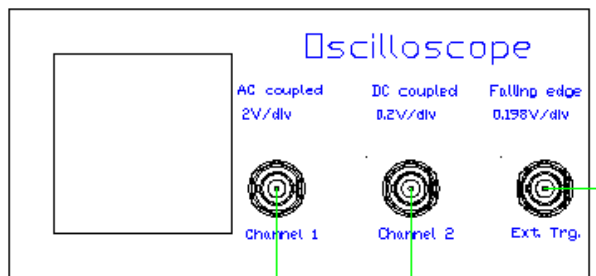

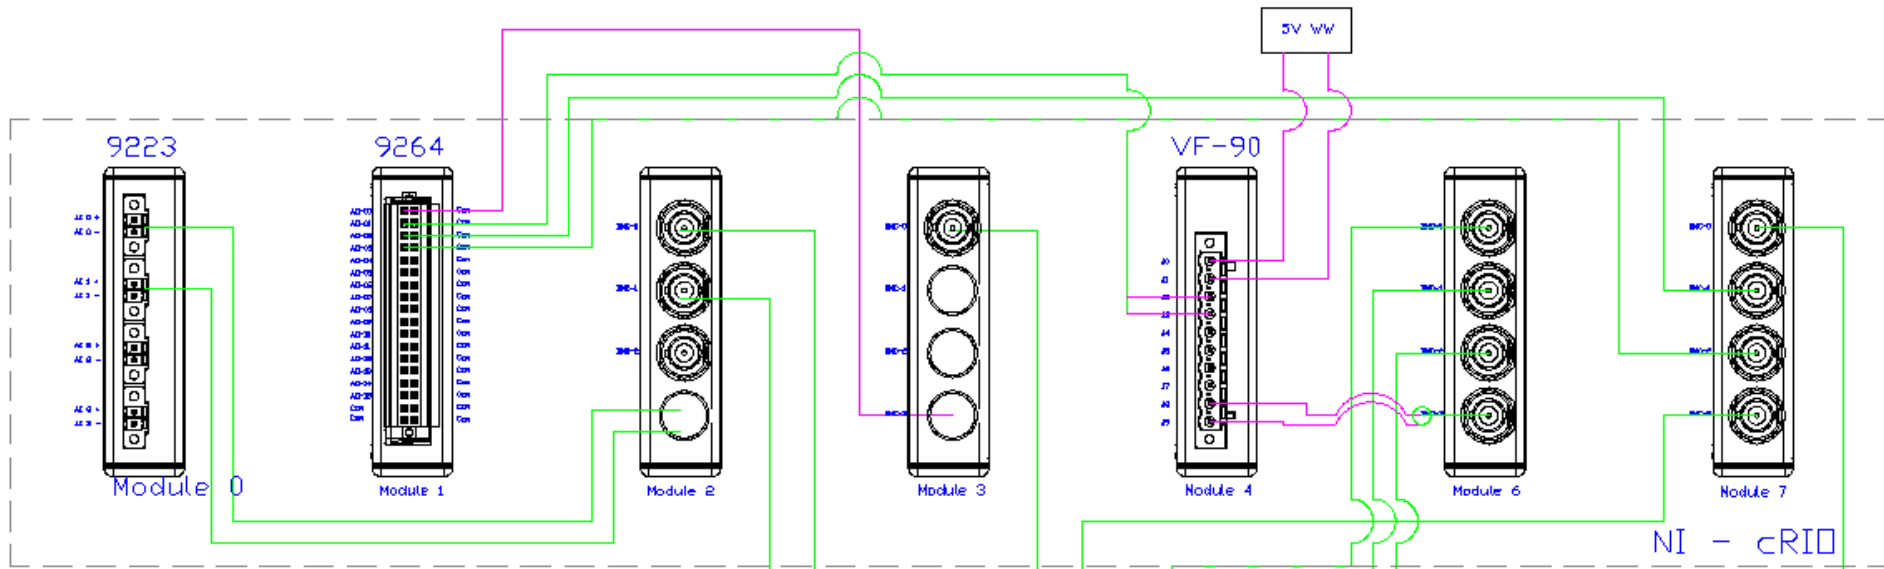

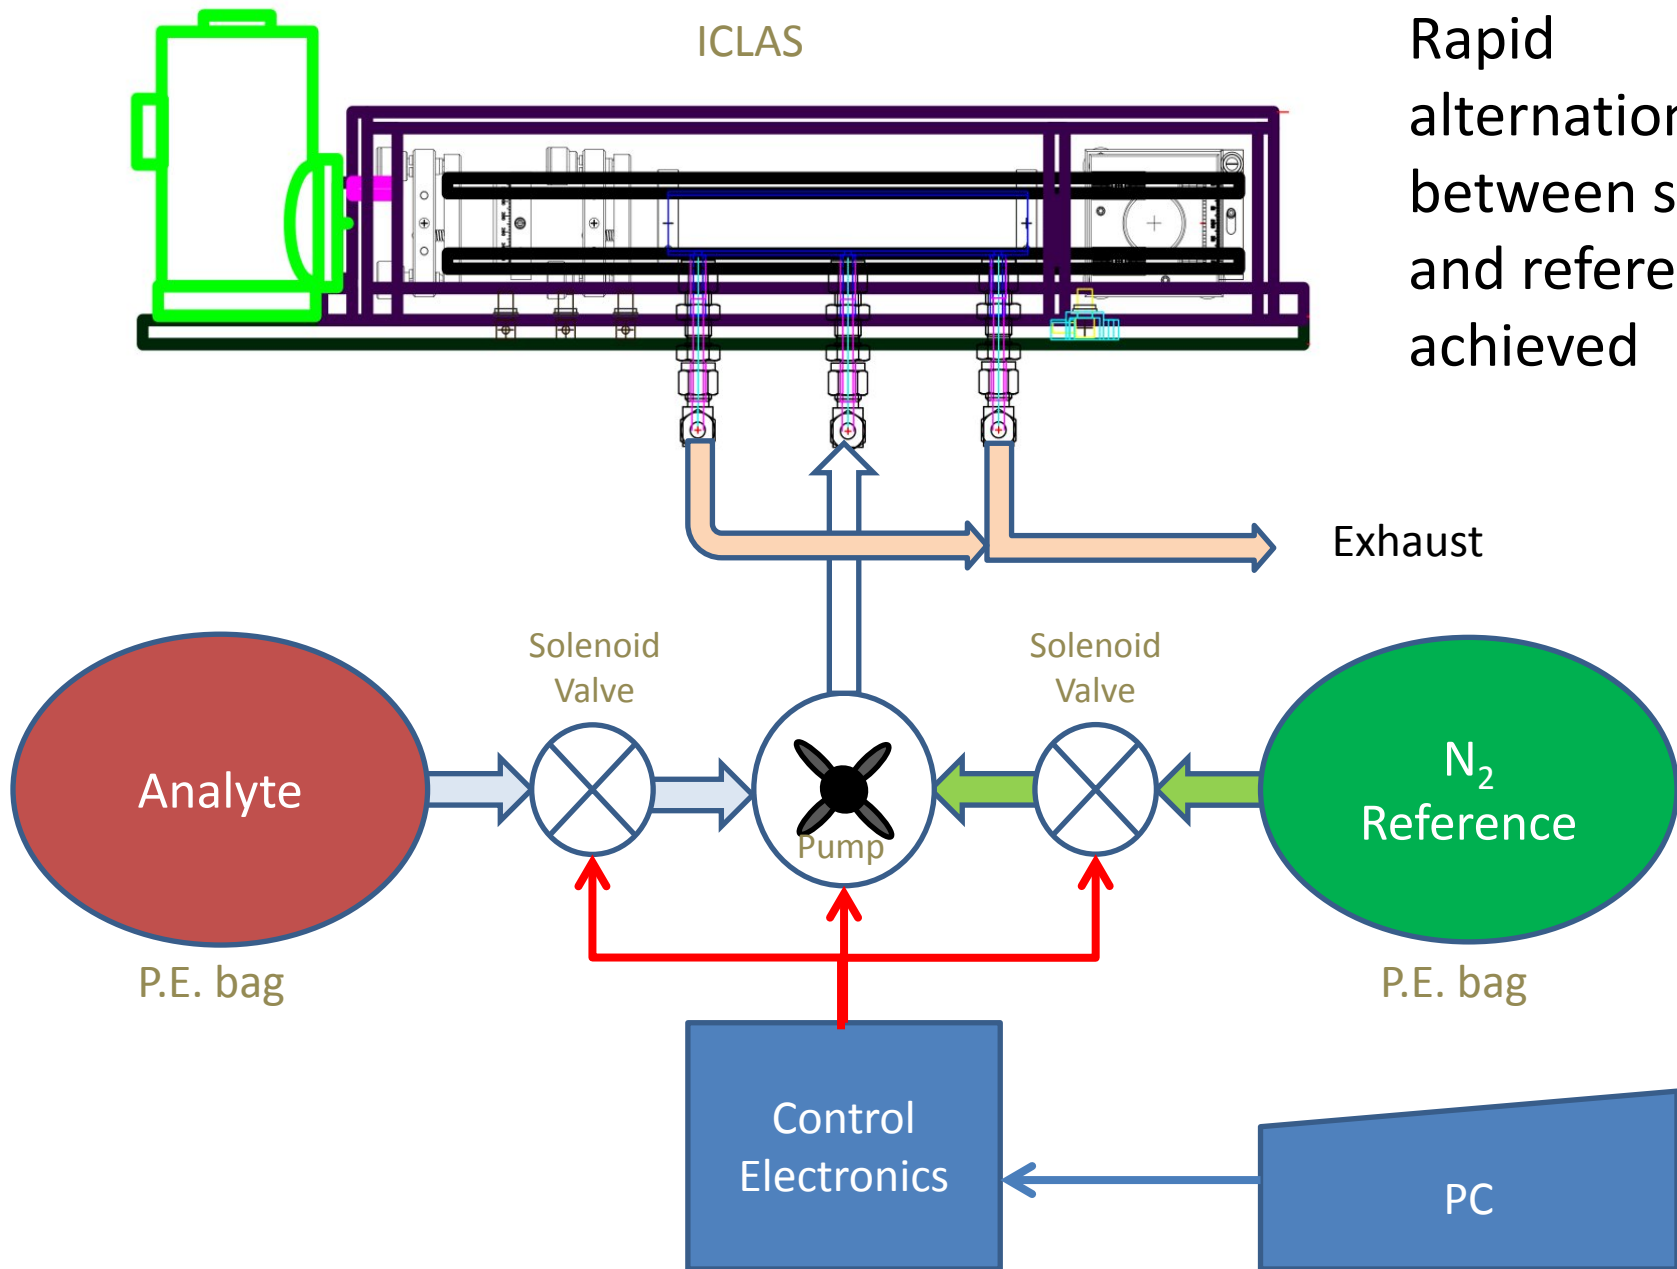

Hyperdog is at Technical Readiness Level 4: Laboratory Brass Board

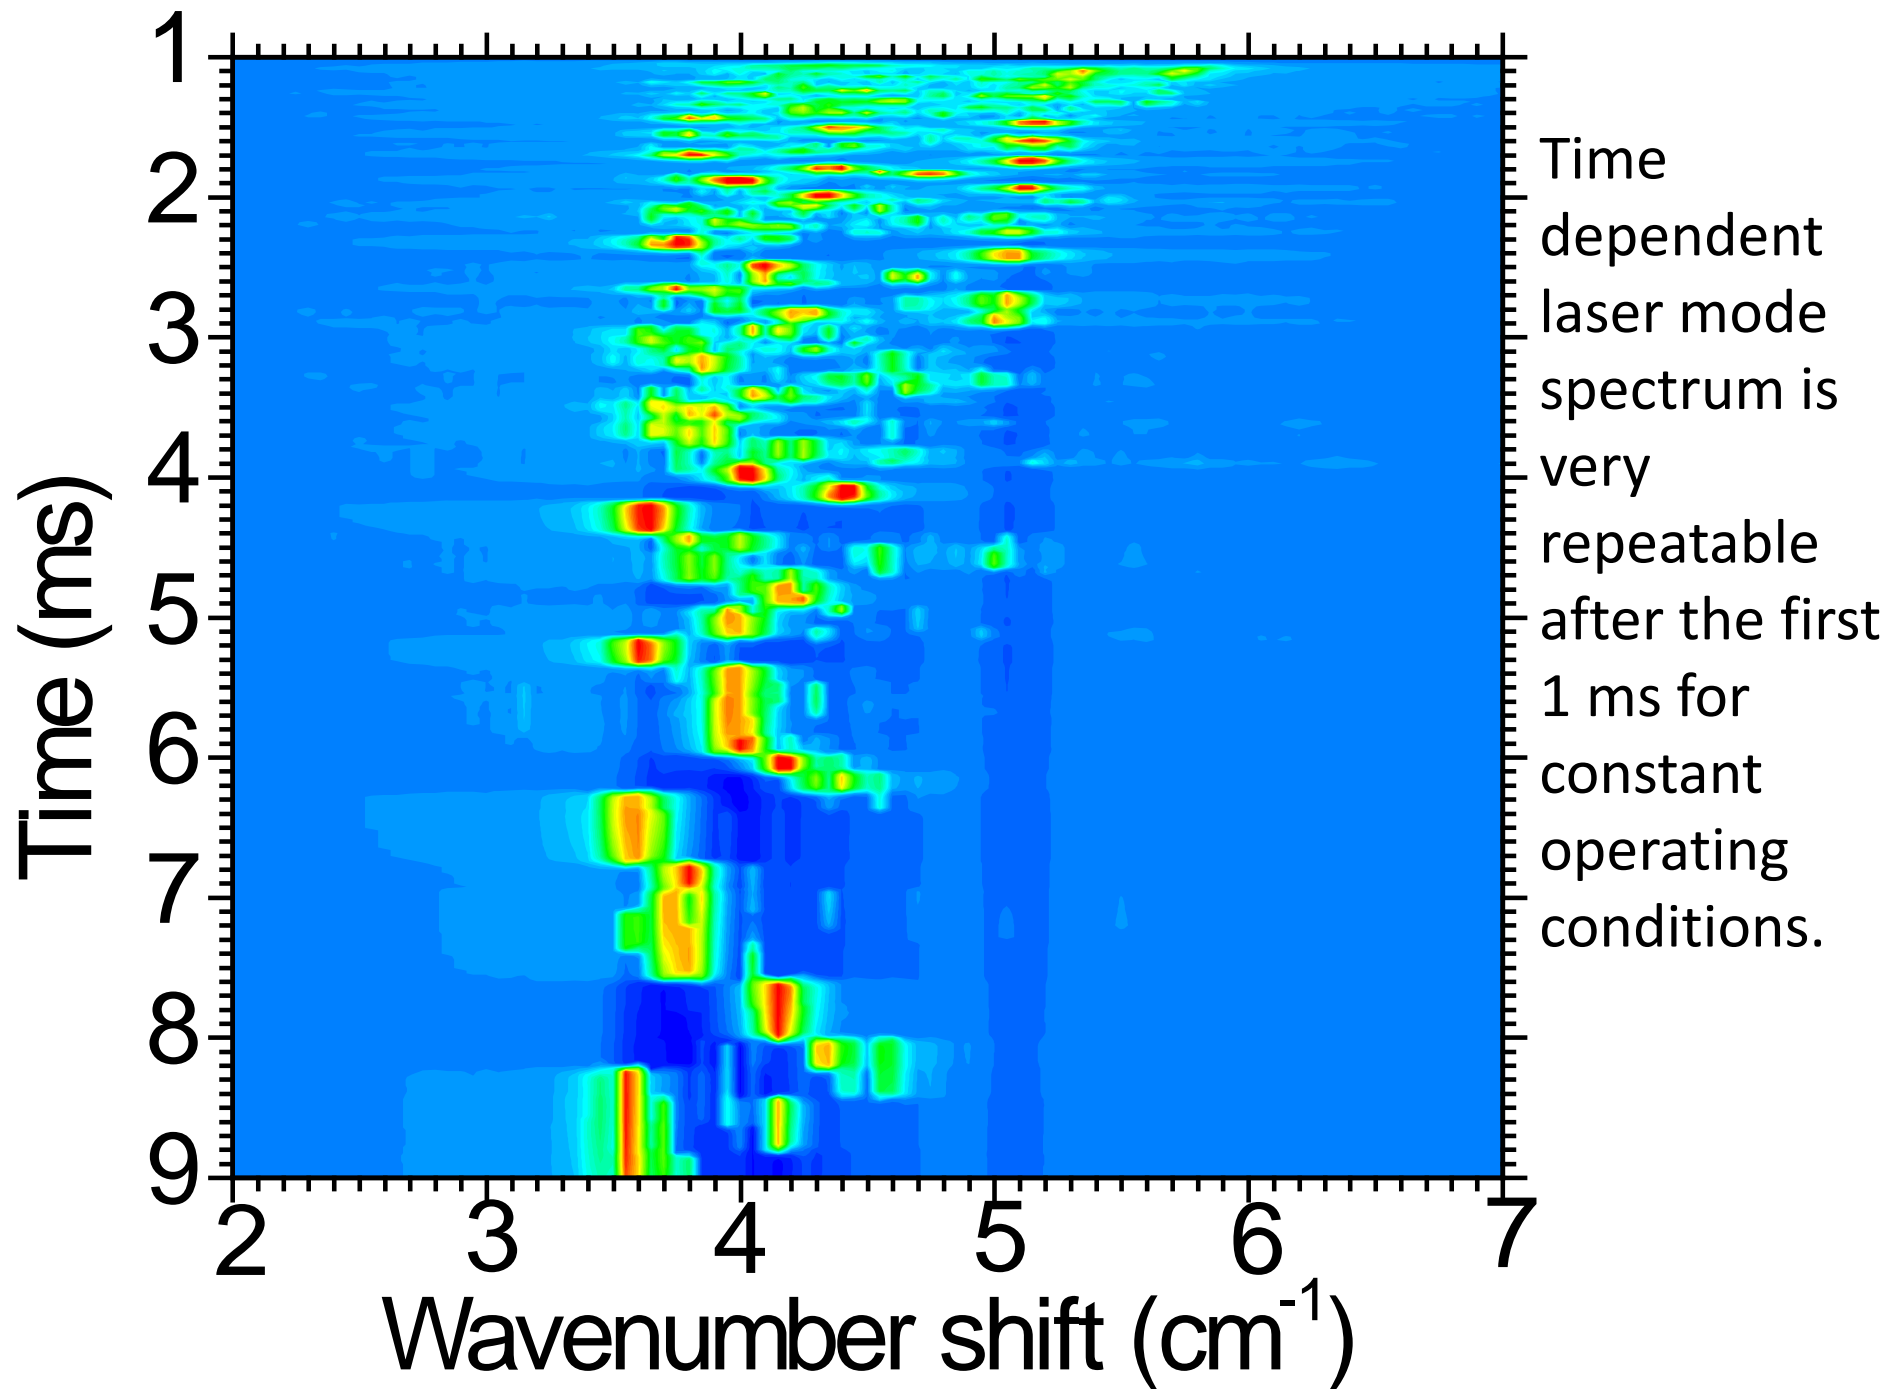

ICLAS

Rapid alternation between sample and reference is achieved

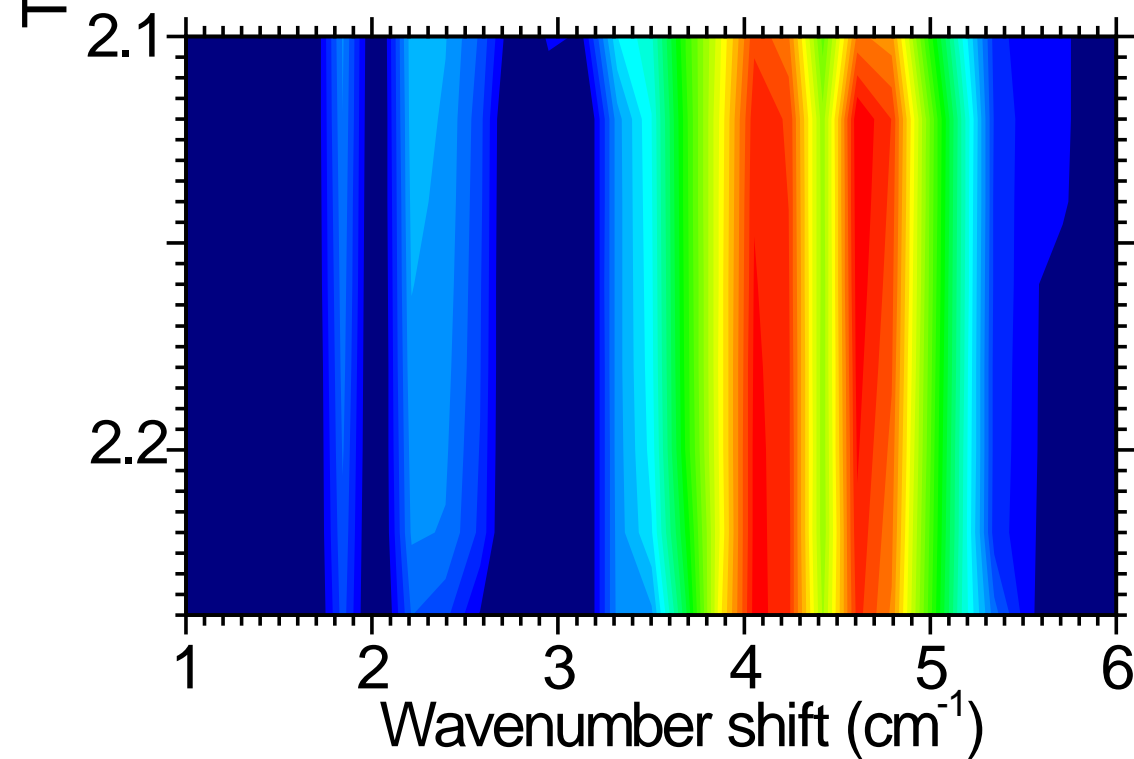

Dry nitrogen in the cavity

Wet nitrogen in the cavity

Integrate over 1.5 ms window

If instead we integrate over all times, and average different laser operation conditions, line shape is a derivative.

Hyperdog is sensitive to absorption coefficients of $\sim 10^{-5} \text{ cm}^{-1}$.

- For molecules with strong cross section (10^{-17} cm^2), this is 40 ppb.
- Considering 25 kHz measurement bandwidth, the noise equivalent absorption coefficient is $\sim 2 \times 10^{-6} \text{ cm}^{-1}/\text{Hz}^{-1/2}$
